## An Address ON ACROMEGALY FROM A SURGICAL STANDPOINT

HARVEY CUSHING

PROFESSOR OF SURGERY, THE HARVARD MEDICAL SCHOOL

### PART I

ONE of the tinnest of the Virgin Islands, a speck named Little Vandyke, almost too small to be designated on a map was once given over—and may still be for all that is known—to the growing of cotton. On this plantation there happened to be born on November 22nd, 1744 of Quaker parents, a boy who a few years later was sent to England to get his education. His chief asset appears to have been a negro "shuffle" which he had learned from his father's slaves, and without this chance accomplishment, so the story goes, the attention of the Reverend Samuel Fothergill of Warrington would probably not have been drawn to the inconspicuous lad. As it was, he gave him a halfpenny, ere long became his guardian and in course of time recommended him to the consideration of his brother Dr John Fothergill of London, whose protégé he was destined to become. This, in small compass was the early story of John Cockerill Lettison the founder and chief benefactor of the venerable society I have the privilege of addressing.

Being the first of my countrymen so far as I am aware to give this Annual Oration, it is fitting that I should call to mind the debt we owe to Fothergill and Lettison for their unflinching kindness to a succession of American students who in the early days came here to walk the hospitals. Fothergill even found occasion to give a helping hand in starting two of our oldest medical schools—at first in Pennsylvania, established shortly before the separation of the colonies, and that in the State of Massachusetts shortly afterwards.

Since I happen to occupy a chair in this latter school, I may recall to you that Benjamin Waterhouse one of its founders and its first Professor of Medicine was a relation of Fothergill's—sufficiently close to call him Uncle—and also that, through Waterhouse, Lettison once presented to Harvard a large and valuable collection of minerals to encourage in our backward land the study of natural science. Thus do some of the medical traditions of my country become interlocked with those of the Medical Society of London.

Men of the calibre of Fothergill and Lettison were universalists in medicine, with interests comprehensive and manifold. This was more possible in their time than in ours and I fear they would have looked askance on the modern tendency to ultra specialization as something foreign to the best interests of our medical guild. I feel somewhat conscience-stricken over this. Since I have chosen to devote my address to a consideration of the surgical aspects of a malady which would have seemed to them, and I fear may to many of you, as small a speck on the medical horizon as is Little Vandyke on the geographer's chart

Though we be in our professional lives with a general training, we very soon find that there are certain malady or phenomena of disease that particularly interest us and from opportunity or force of circumstance concentrate us to engage our attention. It is in this way by progression from the general to the particular that specialization arises and though in the process the field may narrow, at the same time the point of view may broaden. Concentration on a given subject however small makes it loom large to the observer and as Lettison's significant life had an obscure beginning, so the subject I propose to discuss may, if fortune favours be expanded into something worthy of this occasion.

For those of us whose student lives go back to the "Muetie" the pituitary body was too inconspicuous an object to attract much notice or it noticed it as being aside as a vestigial relic of no recognizable importance. There were glimmering to be sure of trouble for the disorder to which Pierre Marie had recently given a name but this was about all. Once pointed out the disorder was unmistakable and yet acromegaly was looked upon for long as little more than a freak of nature which called for staring in its extreme forms fit only for the "side show" to be exhibited with the giant, the dwarf, the idiot woman, and the fat boy whose hypophyseal and not its relationship was as yet unrecognized.

Of the manifold functions of the pituitary body and of its relation to the other glands of internal secretion there was then not the slightest conception. How different a contrast to day when the problem of endocrinology has brought the attention of such a lot of investigators that scarcely a month passes without one or another from one paper or another, being shed on the endoscopic subject! No since the early discovery in bacteriology and in pathology anything comparable to acromegaly to be recorded has been picked up by such. And in Graves' Club and in many others who were the pioneer. But this is not the gold field did not begin until the discovery of an effective substitution therapy for the disease of exophthalmic goitre as it is called in the literature. And when a decade later the real discovery of hypoparathyroidism began to be better understood and the discovery made that all the ductless glands were interdependent and less interdependent than the rest of the profession at large finally admitted but the carrying of the duty as well in consequence of which for popular consumption much twaddle has come to be written on the subject.

There are certain general principles on which right or wrong we have come to base our conception of the function which the ductless glands discharge in the body. The first of these is grounded on the presumption that the secretions of the glands are counterpoised to the functions of the body and that the primary or function for every individual is a so-called endocrine function. It is assumed that each of the secretions is the cause of every malady and each of the secretions is the cause of every malady and its own peculiar clinical syndrome. Some of these already recognized and some few of which are still in the deprivation states like myxoedema, cretinism, encephaloidism, tetany and so on may be produced in man. This is a leap as our working hypothesis is even though it is supported by experimental reproduction of the secretions of glands. Its activity has so far largely baffled us.

This hypothesis has been largely the outgrowth of our experiences with thyroid disorders, and surgery has played no small part in its elaboration. I need recall only a few incidents in the well known story. That Gull's myxoedema was really due to thyroid deprivation, Kocher's experiences with post-operative "cachexia strumipriva" served to make probable, and the success of Haisley's and Murray's substitution therapy left no doubts in the matter. On the other hand, the view advanced by Moebius and Greenfield that exophthalmic goitre was possibly due to glandular overactivity, first suggested by the disclosure that thyroid extracts exaggerated the syndrome, was finally substantiated by Halsted's discovery that experimental hyperthyroidism of the thyroid is characterized by the same histological alterations that are found in the goitre of Graves and Basedow. Thereby it was shown why extirpation of the thyroid in this peculiar form of goitre would serve to ameliorate its symptoms. We accordingly have come, with a good deal of confidence, to speak of hyperthyroidism as opposed to hypothyroidism, of which states the basal metabolic rate now gives us a fairly reliable measure.

Thus, briefly, is the first principle, and on this basis it might well enough have been anticipated that for each of the other glands, acting more or less independently of one another, a clinical syndrome of overactivity and underactivity would by this time have come to be recognizable. However, in the case of the hypophysis alone has this anticipation finally been realized, and though clues serviceable in partially solving the thyroid riddle were persistently followed, even this has been a most complicated task.

An enlargement of the thyroid is for all to see, and in regions where goitre is endemic the surgeon was primarily induced to operate upon cases in which life was endangered or made insufferable from pressure of the enlarged gland on the trachea. Hazardous procedures they proved to be. They were critical enough in themselves, without the unforeseen dangers that lurked in the background of convalescence until, through experience and experiment, it slowly dawned on men's minds that a residuum of thyroid tissue must be left and that the parathyroid glands must be spared if subsequent health—even life itself—was to be maintained.

In comparison, even to get a start in untangling the pituitary problem was far more difficult. Not until roentgenology came to be sufficiently perfected as a diagnostic aid could we really tell with any assurance when the gland was actually tumefied, and its inaccessibility long served to remove it from surgical temptation. Even its experimental removal in animals was difficult to accomplish and gave contradictory results, due in large measure, as we now know, to coincidental lesions of nervous centres adjacent to, and which possibly preside over, the activity of the neuro-hypophysis. In short, hypothalamic injuries long led to as much confusion in the interpretation of the results of experimental hypophysectomy as did the removal of the parathyroids in interpreting the consequences of thyroidectomy.

One of the first questions to be raised in regard to acromegaly concerned its possible relation to the pituitary tumour found in some of the first cases submitted to autopsy, and the acromegalic skeletons in pathological museums the world over were being examined to see whether they showed an enlargement of the sella turcica, which most of them did. However, from time to time examples of acromegaly came to be described in which there was no demonstrable tumefaction of the gland, and, to make the confusion worse, examples of undoubted pituitary tumour, to judge from the syndrome of an enlarged sella combined with a primary optic atrophy and bitemporal hemianopsia, were being put on record which showed no trace whatsoever of acromegalic overgrowth. Quite the contrary, these patients exhibited a medley of inexplicable symptoms, such as dwarfism, sexual dystrophy or infantilism, diabetes insipidus, adiposity, amenorrhoea, myxoedematous atrophies, and so on.

But out of this chaotic jumble order has begun to shape itself, and we are at least coming to close quarters with the riddle. To its partial solution countless persons have made contributions, which piece by piece have been fitted together. The physiologists and biochemists have chiefly

continued their attention on the active substance discovered in extracts of the neuro-hypophysis. The pathologists have, with some measure of success, come to differentiate certain of the hyperplasias and other tumefactions which affect the gland. The morphologists have shown how, in the development of Rathke's pouch, the epithelial anlage of certain of the congenital tumours may arise. The experimentalists have laboriously undertaken to determine the secondary effects of ablation of the gland or of portions of it, the amphibian embryo no less than the adult mammalian animal having been called upon for the purpose. As a combined result of these many disconnected studies, the obscurities of the past are here and there sufficiently clarified, so that we begin to have a partial explanation at least of some of the constitutional effects of deranged pituitary function. Curiously enough, it was not acromegaly, but the reverse condition, that had its first experimental counterpart brought to light.

Following the grudging acceptance of the view that the syndrome of Marie was usually associated with, if not positively due to, a pituitary tumour, it was a natural assumption that the normal function of the gland, whatever it might be, had been abolished, and consequently that its experimental ablation ought to reproduce the symptoms of acromegaly. But those who undertook to corroborate this assumption reported most conflicting results, some claiming that the removal of the gland had no effect whatsoever on the organism, others that its removal led to cachexia and death. No one claimed to have produced anything suggestive of acromegaly, but it was finally observed that certain incomplete extirpations on adult animals led to adiposity and sexual dystrophy, symptoms quite comparable to those which had been seen in clinical cases, and so long it was found that similar procedures in young animals led to skeletal dwarfism and prevented sexual development. Here, then, were experimental states due so obviously to lessening or deprivation of function as to force the conclusion that acromegaly must be ascribable to a counterposed state—namely, to glandular overactivity.

Reduced to simple terms, these early experiments showed that the hypophysis secretes a substance or substances which not only influence growth, but which have a marked effect upon the activity of the reproductive organs. Just what portion of the gland possessed these properties was long a matter of uncertainty. A physiologically active principle had been found only in extracts of the posterior lobe, but most physiological experiments dealt with acute reactions, and it was not until an experimental morphologist took the matter in hand that the growth-stimulating principle was convincingly shown to be the property of extracts of the anterior lobe alone.

Since the time of Galvani the frog has been hailed as the chief contributor to physiology. No less in these present days does the domesticated rat, the biometrical standards of whose life-history have been accurately established, promise to play this important role in experimental morphology. And it is to the rat in the hands of certain investigators that our thanks are due for giving the first wholly dependable and clear-cut results in the hypophyseal problem.

We have learned that menstrual disturbances characterize all forms of pituitary disorder in the female, and strangely enough it was primarily through his studies of the oestrous cycle in rats that Professor H. M. Evans of the University of California first came to investigate the effects of injecting pituitary extracts into these animals. He found that fresh anterior lobe extracts would not only interrupt oestrus in adult female rats but would prevent its onset when given to pre-adolescent animals. He found, further, that when intraperitoneal injections of these extracts were continued over a long period the growth of the animals was greatly accelerated, and that experimental gigantism could thereby be produced.

How excited Lettsom's friend John Hunter, who so ardently sought for an explanation of growth, would have been in these disclosures, whose fundamental importance can hardly be overstated! Not only have they served to lay the growth principle exclusively at the door of the anterior hypophysis, but, for the first time, in the case of any member of the ductless gland series, there has been

reproduced in the laboratory what heretofore has only been theoretically assumed to be a clinical state, due to excessive rather than to a perverted glandular secretion. Dr. Evans's observations have been confirmed in my laboratory by Tracy J. Putnam, who has succeeded in producing some gigantic animals and I may show (Fig 1) the toad of gigantism of one of them with its control

The large female rat on the right was born on October 23th 1925 of a thoroughbred stock. On January 21st 1926 when she weighed 165 gram intraperitoneal injection of a neutral filtered aqueous extract of anterior lobe beef hypophysis in amounts equivalent to about one-tenth of a bee gland daily were begun. The rat was taken on August 5th 1926 at which time she weighed 500 grams.

The small (control) rat on the left also a female of the same stock was born on November 2nd 1925. On January 21st 1926 she weighed 165 grams. She was given injections of commercial anterior lobe extract which proved to be without effect. At the time the rat was taken she weighed 250 grams.

The chief difficulty in the way of success in these experiments lies in the securing of an active extract for the hypophysis which acts as the normal source of supply seem to vary to a great extent in the amount of the somewhat unstable principle they contain and it has been my impression for some years that cattle have a seasonal wave of relative pituitary inactivity. Much labour will have to be expended before we have at our command a reliable extract which can be standardized and kept sterile so that it may be employed for clinical purposes but the discovery that the pars anterior actually contains a growth-stimulating principle will doubtless spur the biochemist to run it down. And when this substance comes to be isolated as it almost certainly will be there will be a different story to tell.

To be sure, these experiments have not reproduced acromegaly, but only gigantism. The nevertheless bring support to the view, long held that these two clinical conditions are closely related, are both hypophyseal in origin, are both ascribable to an excessive secretion of the anterior lobe. As long conjectured, the one (gigantism) probably is the result of a process which has started before the epiphyses have become ossified—which they never do in the rat—whereas the other (acromegaly) is an expression of the same influence which has started after epiphyseal growth has ceased.

If we are indebted to the rat for the illuminating discoveries just mentioned, we are no less indebted to this same animal for more exact information than we have heretofore possessed in regard to the reverse state of pituitary insufficiency. Most of the early observation on experimental hypophysectomy were made on the cat and dog and though they have taught us much, control observations have not been wholly reliable or satisfactory, owing to the slower development and life cycle of these animals and to their great variability in kind. It is quite otherwise

with the rat, and Professor P. E. Smith of Leeland Stanford University has devised an operative procedure whereon hypophyseal or parahypophyseal lesions on this animal may be accurately made with results far more dependable than any heretofore attained. Not only are the symptomatic effects of the operations more promptly and strikingly shown than in other animals, but the possibilities of replacement therapy to atone for the glandular deprivation have been for the first time convincingly demonstrated. In comparison, all antecedent observation on the effects of experimental hypophysectomy laboriously made on the dog are become superseded, and remain of little more than historical interest.

In a recent series of papers written with the collaboration of my late assistant, Dr. L. M. Davidoff we have

FIG 1.—I. Rat (one-third natural size) of experimentally produced gigantism in the rat (as in case of T. J. Putnam).

performed a series of experiments with Dr. Smith on the outcome of some conditions with Dr. Smith on the subject of his hypophysectomy. The results of his hypophysectomy were very striking and have been reported in the literature. The results of his hypophysectomy were very striking and have been reported in the literature. The results of his hypophysectomy were very striking and have been reported in the literature.

The next two rats (Fig 2) were born on October 22nd 1925. The rat on the left was born on October 22nd 1925. The rat on the right was born on October 22nd 1925. The rat on the left was born on October 22nd 1925. The rat on the right was born on October 22nd 1925. The rat on the left was born on October 22nd 1925. The rat on the right was born on October 22nd 1925.

organs are shown. The dwarfed and sexually infantile animal was then given each day a homoplastic hypophyseal transplant, and on April 20th he mated with a female in oestrus and a litter resulted. Daily pituitary transplants were continued until the hypophysectomized animal had almost caught up in weight (268 grams) with its control brother (385 grams). On May 9th, when the photograph (Fig. 4) was taken, the pair was sacrificed and the remaining testis of each is shown in the figure.

The next photograph (Fig. 5) shows two litter mate sisters born on December 25th, 1923, the animal to the right having been subjected on February 5th 1924 to an injury of the hypothalamic region without hypophyseal extirpation. On February 27th, 1925, this animal weighed 840 grams to 299 grams for the control. The animal was sacrificed on this date, and an extensive atrophy of the sex apparatus was disclosed, the other ductless glands being of normal size.

measures, surgical or otherwise. These several syndromes have come to have a varied and somewhat confusing nomenclature, which must for a moment detain us.

#### NOMENCLATURE

When terms such as myxoedema, exophthalmic goitre, cretinism, acromegaly, and so on, descriptive of certain clinical states of unknown etiology, become, through use, thoroughly established, it is difficult to uproot them. Even to suggest doing so is perhaps discounting to those who planted the seed. Descriptive terms, however, may prove to be exceedingly inconvenient from a nosological stand-

FIG. 2—Littermate brothers, showing effect of early hypophysectomy in producing dwarfism with atrophy of the endocrine system. Measurement in centimetres (P. L. Smith)

FIG. 5—Experimental hypothalamic syndrome. Measurement in centimetres (P. L. Smith)

Taken in conjunction with the observations by H. M. Evans and his co-workers on experimental anti-gigantism, these illustrations of the counterposed state, to the study of which P. L. Smith has confined himself, show what an immense field has been opened up for future investigations of pituitary function, which can be far more precise, owing to the species chosen for experimentation, than any heretofore undertaken.

This is only the beginning of what we shall some day know about this amazing structure which conducts the endocrine orchestra and brings therefrom harmony or disharmony, overtones or undertones, according to its physiological mood. But let us see, from the striking results already attained what light may be thrown upon the several clinical syndromes we have come to recognize, and in what ways the experiments concern our therapeutic

point, and were there any choice permissible it would be preferable to cling to such non-committal monisms as the syndrome of Gull, or of Graves, or of Marie, as we have done with Addison's disease.

The particular inconvenience in the case, for example, of *acromegaly*, is that the term, which is now associated in the minds of all with a state due to hypophyseal overaction, merely described an enlargement of the acral parts of the body. It accordingly gives no opening for an opposed term to describe the now recognized counterstate of all that "*acromegaly*" once conveyed, for *acromicria*, a smallness of the extremities, would mean nothing at all, and other designations that have been suggested are no more satisfying.

Had the designation *macrosomia*, implying overgrowth in general, suggested, I believe, by Hastings Gilford as appro-

prate for Maries syndrome, not fallen on sterile soil, *acromegaly* would have been a convenient term for the growth deficiencies which are the striking features of the reverse state. Adipogenital dystrophy merely calls up a syndrome which may not necessarily be hypophyseal at all and though such eponyms as Itsek's disease, Lorain's disease and Simmonds' disease bring to mind certain recognizable clinical types of pituitary deficiency, there are still others unnamed.

However much those who know the appeal of medical history may wish to dwell upon and cherish the names of its eponymous heroes, it would be better for medical terminology to abandon or at least to modify symptomatic

associated tumour or may properly add a fourth, *apituitarism*, indicating the complete loss of pituitary activity.

Let us now consider briefly what are the clinical expressions of the four gradations of pituitary pathological lesions (some of which have definite surgical bearing) they are brought about. We may summarize the effects of complete glandular deprivation.

#### A PITUITARISM

Does such a condition *acromegaly* hypophyseal or due to acute destruction of the gland whether by operation, pathological, or surgical process *acromegaly* or *apituitarism*. This is an

FIG. 3—Litter mate brothers showing comparative size of testes of control and of dwarf three months after hypophy ectomy. Measurement in decimetres. (P. E. Smith)

designations and eponyms when they no longer convey what a single term should convey. So in the case of the thyroid disorders, though the terms Graves's or Basedow's disease and exophthalmic goitre for the state counterposed to myxoedema and cretinism, have long served a useful purpose, they are coming to be superseded by hyperthyroidism and hypothyroidism, as being more precisely descriptive, particularly since we have grown to recognize types of thyroid overactivity not associated with exophthalmos.

For similar reasons some years ago the terms *hyperpituitarism*, *hypopituitarism*, and *dyspituitarism* were suggested as correspondingly proper substitutions for *acromegaly*, for its counterposed state, and for overlapping types of the two and though these words are quite a mouthful, and what is more have a mongrel derivation hyper and hypopituitarism were phonetically quite impossible. To these three terms which of course apply merely to varying grades of glandular activity and have nothing to do with the presence or absence of an

important question for the surgeon. In the hypophyseal tumour, if it is to be removed in its entirety without serious ill effects, the problem of treatment of the tumour must be representative of the commonest form of tumour affecting the gland, for the commonest form of tumour affecting the gland becomes greatly simplified. It can be other hard cases consequences are likely to occur or may occasionally occur the operation or total or subtotal hypophysectomy may be deferred until some method of substitution therapy has been found sufficiently effective to offset them.

It is obviously a matter to settle in the laboratory in the clinic. But the laboratory so far has given conflicting results. My own impression is that the extirpation of the gland provokes a peculiar train of events passing from exophthalmos to coma and to death. It is a sequence to be sure, more likely to appear in older animals than in younger animals, but even in the older animals the same operative procedure short of total extirpation leads to no comparable ill effects. On the other hand, Dandy and Ralston have recently reported a case of acromegaly, claiming that the operation of subtotal hypophysectomy

There have been, all told, 81 verified examples of these tumours in my series, and, as it happens one of the patients, a dwarf who exhibits certain evidences of senium praecox suggestive of progeria, is at this writing under observation in the hospital.

FIG 10—Pituitary infantilism with diabetes insipidus due to a crano-pharyngeal pouch (Rathke's tumour) (Child with father)

(Surg No 25031) A girl, aged 3½ years, a child of Hungarian parents, was originally admitted on October 21st, 1925, owing to a rapid loss of weight associated with head aches, vomiting, polyuria, and polydipsia, of four months' duration.

She was (Fig 10) an extremely undersized, undernourished child, weighing only 20 lb and 34 in in height. The optic discs showed marked pallor, to gross tests there was a bilateral loss of vision, and the x-ray revealed a slightly widened sella with superimposed calcification (Fig 11)\* which left no doubt as to the diagnosis.

An operation was not thought advisable and she was discharged, but a month later, owing to an increase of symptoms with subnormal temperature, somnolence, and an exaggeration of her polyuria, she was readmitted to the hospital and was operated upon on November 17th, 1925.

By the usual right frontal osteoplastic approach (Figs 12 and 13) a crano-pharyngeal pouch cyst was encountered and was withdrawn apparently in its entirety (Fig 14). The operation was extremely well borne, her headaches completely subsided and the symptoms of diabetes insipidus ceased. Subsequent to her discharge she began to gain in weight, and there was a marked improvement in vision.

Following an attack of scarlet fever, and because of a tendency of headaches to return she was brought back to the hospital for observation on May 16th 1927. During the eighteen months' interval, though she has increased 10 lb in weight, she has

these cysts, even when there is no pre-existent polyuria, diabetes insipidus may be produced by contusing the deformed hypothalamic region. The fact that she has not grown, or grown very slightly, since the operation makes it probable that the anterior lobe has been permanently damaged either from the long compression by the tumour or in the course of its removal. And this brings up again the point from which we cannot get far away—the essential need of substitution therapy if we are to deal effectively with these secondary symptoms, whether they are associated with a tumour or not. In this particular child Dr Putnam is attempting to see what can be done to stimulate growth by parenteral injections of an active anterior-pituitary extract he has elaborated, fully realizing, in view of Dr Smith's experiences, that homoplastic transplants, were they obtainable, would be far more effective.

FIG 14—Portions of the crano-pharyngeal pouch cyst removed at the operation

### 3 Hypopituitary States Associated with Chromophobe Adenomas

Of all pituitary syndromes, these are most often encountered, and they occur almost exclusively in adult life. To May 1st, 1927, there have been in my series 188 histologically verified examples—almost three times as many as the chromophile adenomas associated with acromegaly.

Though the disorder is a very common one, as common in all probability as goitre, one would hardly venture to make a diagnosis in the absence of definite local evidences of the growth, and since these patients, with rare exceptions, have already attained their full stature, the constitutional evidences of diminished glandular function are often inconspicuous, being limited to the well known cutaneous changes, with a tendency to adiposity and loss of hair, to sexual dystrophy, and so on. Unquestionably these states in

FIG 12 and 13—11 patient ten days after operation showing the customary incision in the scalp exposing the hypophyseal region by an osteoplastic flap

grown a scant half inch. However her vision is apparently normal, and the x-rays show no trace of suprasellar calcification.

That this child should have recovered from the diabetes insipidus is unusual for in the effort to dislodge one of

these minor grades, when the patient has no particular complaints, entirely escape attention, and, indeed, even when deficiency symptoms, in addition to those of tumour, have become unmistakable, it is not unusual for the patient to be treated as a presumptive case of myxoedema.

\* This will be published in our next issue.

It was the experimental reproduction of similar states in adult dogs (without the tumour signs of course) that gave the first clue to these disorders, and what was then not so clear the symptoms in all probability are almost wholly due to deficiency of the anterior lobe from which the adenomatous tissue originates. For even though the tumours may attain a large size and extend into the cranial chamber, they rarely cause hypothyroid symptoms.

To be sure one sees occasional exceptions to the usual syndrome—namely, in adult patient with primary optic atrophy, bitemporal hemianopsia, and a ballooned sella, coupled with the constitutional evidences of diminished pituitary activity. We have, for example, encountered a typical chromophobe adenoma in a young child, and I have recently operated upon a middle-aged woman with primary optic atrophy and bitemporal hemianopsia associated with a sella turcica quite normal in size, in whom, owing to the absence of any hypopituitary symptoms, a small suprasellar meningioma was suspected. Consequently the chiasmal region was exposed by a transfrontal operation, and I found to my surprise a small encapsulated chromophobe adenoma which had arisen from the upper part of the gland and had pushed its way up under the chiasm without having distended the sella in the least.

But this was a most unusual experience. Ordinarily in these cases there is a greatly distended sella, and the usual operation is conducted from below by what is known as a transphenoidal procedure, in the course of which as much of the exposed growth as is thought expedient is spooned or "sucked" out with the sole purpose of counteracting its local pressure effects. The operations in other words, are not undertaken with any expectation of altering the co-existent hypopituitary symptoms. For these either remain unaffected if, as is usual, nothing but adenomatous tissue is removed, or they may be exaggerated if any physiologically active though compressed remnants of the gland happen to be removed together with the tumour tissue, or they may, indeed, be lessened in severity should such remaining normal portions of the gland be enabled to resume their normal activity because of the decompression. Though we have seen examples of all these secondary consequences of the operation, its main purpose has been to preserve or to restore vision, and the degree of hypopituitarism has not entered largely into the question.

### C DYSPIUITARISM

Though this term was originally used to cover all clinical expressions of disordered pituitary function, it would seem preferable to-day, now that these states are becoming clarified to restrict it to that particular group of cases in which preceding hyperpituitary symptoms have become overshadowed by those of the reverse state. The experimental counterpart of dyspituitarism would be produced, accordingly, by hypophysectomy in a giant rat, which would impose a deficiency syndrome on the established hyperpituitary gigantism. Though such a state as this, so far as I am aware, has never been studied experimentally, there is clinico-pathological evidence that such a transitional syndrome exists.

In a recent paper from my clinic by Drs. Dott and Bailer, attention was drawn to certain mixed types of adenoma of which fourteen definite examples have so far been identified out of our total verified cases of 271 adenomas of all kinds—not a large proportion to be sure, but all questionable cases have been excluded. What first called attention to these transitional adenomas formerly classified as chromophobe was the fact that it has been sometimes difficult to tell clinically whether the patient's malady has been accompanied by a deficiency syndrome from the outset, or whether it may not in its early stages have been hyperpituitary, to judge from suggestive traces of pre-existing acromegaly or gigantism.

However since in these mixed or transitional cases the surgical problem does not differ from that discussed above under hypopituitarism, due to chromophobe adenoma we may pass to the consideration of our final and most important group of cases, to which all this long story is merely preliminary.

### ON THE EFFECTS OF RADIATIONS ON PATIENTS AND RADIOLOGISTS, AND ON PROTECTION\*

BY

SIR HUMPHRY ROLLESTON, BART., K.C.B., M.D.,  
Ho. D.Sc. D.C.L. LL.D.

REGIUS PROFESSOR OF PHYSICS IN THE UNIVERSITY OF CAMBRIDGE  
PRESIDENT, BRITISH INSTITUTE OF RADIOLOGY

#### Introduction

IN December, 1895, the late Professor W. K. von Roentgen of Würzburg, by what has often been described as a fortunate accident when working with a Crookes's tube, forestalled Crookes and others who were working on the same lines and within measurable distance of the momentous discovery of X-rays. Radiology is therefore hardly thirty-two years old, and many of us can compare the face of medicine now with what it was in the days that were earlier. It is to the credit of our profession, often conservative in adopting new ideas and advances, such as those so long advocated by Lister, that the first practical application of X-rays was in surgery and medicine.

Youth has the advantage of enthusiasm and a more or less uncharted field of inquiry before it, and the advances in medicine made by radiology in such a comparatively short time have been revolutionary, thus contrasting with

the changes made in the practice of medicine by the discoveries of percussion by Leopold Auenbrugger (1761) of Vienna, and of auscultation by Laennec (1819) which were slow to take effect. In the preface of the English translation of Laennec's *L'Auscultation mediate* (1821) Sir John Forbes hazarded the prophecy, which indeed was fairly correct, that its general adoption was extremely doubtful. The history of the ordinary method of physical signs when compared with the dramatic rise of radiology and its new revelations suggests some thoughts. Radiology like bacteriology, so frequently appears to clinch the diagnosis in a case which still remains doubtful as the result of ordinary physical examination, that when an X-ray department is available there is a tendency to fly at once to it for a solution, without going systematically through the time- and thought-consuming process of routine examination. This is the easy path and line of least exertion which the student resident or busy physician may be unable to pursue, but unless and until radiological outfit becomes like the wireless or the low priced motor car, within the reach of all medical men there is a nucleus before the man who leaves the well equipped hospital to practice in a remote and isolated district where he performs his duties on his own resources and finds that for him radiology is a lost art. Since the siren-like call of radiology has a potential influence for harm clinically and otherwise, let a useful example or exhaustively investigated and available methods of ordinary examination be the guiding aid of radiology.

There are three personal aspects of radiology to which reference may be appropriate: (1) the radiologist in the medical profession, (2) the patient, and

\* The lecture which was delivered before the Pöntzen Society and the Electro-therapeutic Section of the Royal Society of Medicine on June 30th has been slightly abridged.

effects of radiations on patients, and (3) the physical effects of long-continued work in radiological departments on those thus engaged.

### 1 *The Position of Radiologists in the Medical Profession*

It is natural that there should be a wholesome rivalry between the pure clinicians and the radiologists, analogous to that between the clinicians and the laboratory workers, as to who shall be regarded as the decisive makers of the diagnosis, it is therefore important that clinicians and radiologists should be in constant touch and consult frequently on equal terms, each thus acquiring the special knowledge and perspective of the other. Like the bacteriologist the radiologist should form part of the team for clinical practice and research, and should not be segregated in his department. The radiologist is the helpful colleague of the clinician, and they are both judged as regards their accuracy or mistakes by the conditions found on the operating table or in the *post-mortem* room, it is therefore most essential that the radiologist should, like the clinician, follow through to final demonstration the cases on which he has expressed an opinion, and be imbued with pathological knowledge. Indeed, radiology enables them to see through a clinical telescope and so, like the operating surgeon, though with less inconvenience to the patient, to demonstrate "the pathology of the living." To discover the pathology of the living correctly is the aim of diagnosis, and to do so demands a thorough knowledge of morbid anatomy as it appears in the *post-mortem* room. By their attendance as far as their many engagements will allow, at operations and at necropsies, and by checking their films with the lesions revealed there, radiologists will not only greatly improve their powers of interpretation and diagnosis, but will strengthen their alliance and reputation with their professional colleagues, for in this way their experience will become unrivalled.

There are also the important factors of maintenance of a high standard of efficiency and unity of aim within the specialty of radiology to be considered, those, such as the late Sir Archibald Reid, who laid the future of radiology most at heart were insistent on the establishment of diplomas in radiology such as those subsequently instituted at Cambridge (1919), Liverpool (1920), and Edinburgh (1926). This is a valuable means of insuring a thorough education and training for future radiologists, and is fulfilling its object. There has been a want of a central institute where all persons interested in radiology—medical men of all kinds, physicists, technicians, and manufacturers—can meet on the common ground of the advancement of radiology to discuss all matters of radiological interest, to exchange knowledge and take combined action, when necessary, where teaching can be centralized and research facilitated, where a library of books of reference and periodicals and an ever growing collection of films are available and generally to further the development and welfare of radiology. With these objects the British Institute of Radiology, incorporated with the Roentgen Society was, after long-drawn-out discussions, finally established. The Articles of Association provide that "no member or associate who is not a registered medical or dental practitioner shall accept patients for diagnosis or treatment except under the personal supervision of a registered practitioner" (Article 12) and, on the action and with the approval of the General Medical Council Section 3 (c) of the Memorandum of Association, which provides for granting diplomas and certificates of merit and efficiency has been amended by the addition of the following words: "and that the holder of such diploma or certificate is not thereby entitled to undertake the medical diagnosis or treatment of patients except under the personal supervision of a registered practitioner."

With the rapid growth of radiology it is clearly becoming clear that specialism inside this branch must be anticipated and that the radiological technique necessary for the dental, neurological, neurological and other special departments will inevitably lead to the subjects becoming the life's work of certain men, as this will provide opportunities for intensive study and the accumulation of

more accurate knowledge it should be welcomed as evidence of the success of radiology in the present, and of its promise in the future. Not only will patients benefit by this increase of efficiency, but in certain branches, for example psychology, then comfort and safety depend on special knowledge and technical skill.

### 2 *The Physical Effects of Radiations on Patients*

The untoward effects of radiations on patients are usually acute and in the form either (1) of burns and epilation as a result of excessive dosage, or possibly in very rare instances from idiosyncrasy, or (2) of acute constitutional symptoms which have become more prominent since the introduction of intensive x-ray treatment of deep-seated abdominal malignant disease. The production of burns and dermatitis may entail legal actions for compensation, and a blow to the x-ray worker's reputation. Although the untoward effects of radiation are usually acute, patients frequently exposed to radiations may become gravely ill, but in the cases thus treated it is often difficult to decide between the influence of (a) radiations on the haemopoietic tissues, and (b) of the involvement of the blood-forming tissues by the disease from which the patients are suffering, thus infiltration of the bone marrow by malignant disease or lymphadenoma, or leukaemic change, may be regarded as responsible, cases of aplastic anaemia after x-ray and radium treatment for chronic leukaemia have indeed been reported (Ross, 1925; Whitcher), but are open to alternative explanations.

The acute constitutional symptoms (Roentgen-ray intoxication, radio-toxaemia) are of several degrees. The comparatively mild symptoms of malaise, lassitude, loss of appetite, nausea, and occasional vomiting, comprised by Beclevé (1921) to sea-sickness, have been ascribed to the effect of ozone and noxious nitrous gases in all ventilated x-ray departments, on the other hand, they may be minor results of the process responsible for the graver manifestations. A distinction has been drawn by Mallet and Coliez between (a) the immediate and comparative mild effects, which usually pass off in forty-eight hours, and (b) the more severe constitutional symptoms with delayed onset, fortunately uncommon, and consisting of uncontrollable vomiting, offensive diarrhoea with the passage of blood, abdominal pain and distension, fever which may reach 104° F. profound prostration, progressive cardiac failure, and sometimes a fatal issue. These grave symptoms have been explained in several ways, experimentally it has been shown by Whipple, in collaboration with Hall and with Warren, that massive doses of x rays over the abdomen produce a primary epithelial necrosis in the mucous membrane of the small intestine, which may be entirely responsible for a non-specific intoxication (that is, not due to any constant bacterial infection). According to Mottin and Kingsbury (1924) necrosis is preceded by interference with the production of mucus and invasion of the mucosa by bacteria, which pass into the blood, and thrombopoeia follows. Another view is that there is a general flooding of the circulation with protein products of cells destroyed by the action of radiations, and that the intestinal lesions are secondary. That intensive penetrating radiation of the abdomen is prone to be followed by the severe constitutional symptoms is confirmed by clinical experience, and it would seem reasonable to believe with Whipple that the intoxication is derived from the intestine on the other hand the occurrence of these same symptoms after irradiation of large tumours in the neck and mammary region shows that extensive cell destruction in parts of the body other than the abdomen may have a similar toxic effect. It has also been suggested that acute constitutional manifestations are anaphylactic and due to sensitization to proteins liberated by leucocytes and other tissues damaged by a previous radiation. That this is not applicable to all cases is proved both experimentally (Hall and Whipple) and clinically by the occurrence of acute symptoms after the first irradiation (Jadass and Pemberton).

*The Altered Stimulating Effect of Radiations*—The bacterial effects of radiation on ovarian disorders have been ascribed to a stimulating influence, but the recent work of Parkes, Fielding, and Bramwell seems to show

that it is due to a compensatory regeneration of ovarian tissue after the ovaries have first been destroyed by irradiation. The conclusion of Degradin that any apparent stimulating effect of radiations is a compensatory phase only and is invariably followed by more or less pronounced functional or organic deterioration, is probably correct.

The view that small doses of radiations stimulate malignant growths to greater activity put forward by Waring and Swift and used as an argument in favour of a large dose of radiations, is supported clinically by the occurrence of cases showing more rapid growth after radiation; this, however, may be an argument of the *post hoc, propter hoc* kind for the increased size of a tumour after radiation may, as Waring pointed out, be due to factors other than increased activity of the malignant cell—for example, to vascular engorgement, infection, or serous and haemorrhagic infiltration. While increased proliferation of the neoplastic cells is a result of direct stimulation by radiations appears from numerous observations to be improbable, it is reasonable to believe that damage done by radiation to the surrounding stroma whereby their defensive power is inhibited may explain increased spread of a growth after irradiation. Finally, we reach the conclusion that there is no convincing evidence in favour of the view that small doses of radiations directly stimulate neoplastic cells to more active growth.

**Method of Action of Radiations on Malignant Growths.**—The views of Brishford Murphy and Nakahara and Fung, to the effect that the malignant cells are not acted upon directly by the radiations so much as indirectly by the increase of the defensive activities of the surrounding tissue through fibroblastic proliferation, lymphocytic reaction and obliteration of the vascular supply are in opposition to the conclusion that the malignant cells are killed outright by the radiations. The influence of a general noxious effect, induced by radiation on the local tumour was raised by Opitz and Kol and there is the possibility that cytotoxins produced in the tumour may play a part but Fung's recent work is in opposition to this attractive idea.

[The varying radio-sensitiveness of tumours and of their constituents (malignant cells and stroma) and Bergonie and Tribondeau's law as to the greater radio-sensitiveness of undifferentiated cells, such as lymphocytes than of the more highly developed cells, such as columnar celled or the keratinized squamous-celled carcinoma were mentioned and a discussion was drawn between the two aspects of the changes in the cells and in the stroma. The initial radio-sensitiveness of a tumour and the later acquired resistance after repeated radiation were also discussed and Poussy and Fung's views as to the explanation were quoted. The possibilities of rendering malignant cells specially sensitive to radiations by artificial means such as impregnation with lead, was mentioned.]

### 3 The Physical Effects of Long continued Work in Radiological Departments on those thus Engaged

Soon after the discovery of x rays the harmful effects on the operators and patients became known. In March 1896 information arrived to the effect that Funon and Dr W. J. Morton had suffered with conjunctivitis as the result of some hours exposure (*Nature* 1896 Jan 421). The skin lesions x-ray or radio-dermatitis, were noticed in the same year, and in 1897 D. Walsh first directed attention to acute constitutional symptoms by describing them in x-ray workers in one of whom the symptoms disappeared when the abdomen was shielded by lead. Since then a very considerable literature has grown up on the subject of the untoward effects of radiations. In 1911 Krause stated that fifty-four fatal cases of cancer had been traced to radiations and in 1922 Ledoux Lebard estimated that one hundred radiographers had paid this penalty. In addition, the first noted by Alber Schönberg is now fully recognized physiologically and therapeutically. In 1905 Brown and Osgood found unsuspected sterility in eighteen persons employed in manipulating x rays from half an hour to four hours three times a week for from two to six years—a somewhat startling revelation.

The blood changes in x-ray and radium workers—namely

anaemia, leucopenia, and lymphopenia—are of special importance as they can be detected in an early stage and so further progress, towards grave aplastic anaemia, can be prevented by cessation of exposure. This method of early recognition and prevention being analogous to that practised in lead workers. The leucopenia immediately following irradiation is due to destruction of leucocytes in the circulation, as is shown by their remains seen in blood films whereas the prolonged leucopenia is the result of injury to the haemopoietic tissue. The two grave blood disorders seen in persons long exposed to radio-active substances are acute aplastic anaemia and leukaemia of which Jaulin has recently collected nine and eight examples respectively. It is generally believed that the radiation acts by producing aplasia of the bone marrow but from experiments on guinea pigs Fabricius-Moller believes that a large dose of x rays first produces the leucopenia and then after a week thrombopenia with the haemorrhagic diathesis and that the anaemia is due to haemorrhages. Hann and Faber, however, contend that the x rays cause a quence of events the colour index in the experimental animal should be very low which is not the case as indeed Fabricius-Moller admits. The occurrence of leukaemia was ascribed by Weil and Fung to a stimulating action of radiations on the bone marrow—an explanation which raises the vexed question of the existence of a stimulating influence of radiation.

Considering the relatively large number of x-ray workers radium appears to have a still smaller tendency to cause aplastic anaemia. The few cases reported are to be almost confined to x-ray workers for there is only one exception—the case of myeloid leukaemia reported by Weil and Loefer in a thorium worker.

The personal knowledge that peptic ulcer of the stomach and duodenum and malignant disease of the alimentary canal have occurred in radiologists of long experience coupled with the gastro-intestinal lesions of the constitutional symptoms occasionally seen after repeated applications of x rays to the abdomen naturally creates the suspicion that there may be more here than mere coincidence. It is true that peptic ulcer is rather frequent in medical men who are no radiologists and also that radiologists may like other medical men suffer from the result of irregular meals and too regular smoking. Experimentally massive x-ray exposure of the abdominal cavity causes acute damage of the intestinal mucosa and Lazzari, Barlow obtained similar results with the gamma rays of radium it might therefore be thought that the x-rays though long continued exposure might cause chronic inflammation of the rather extreme proliferative changes in the stomach and exposure of the mucosa of the stomach. Wolfer produced a chronic peptic ulcer. The peptic ulcer cannot be regarded as a radiological lesion but it may be worth while to bear the possibility in mind.

### Detection of Lead in Radium Workers

Soon after the recognition that prolonged exposure to x rays carried with it ill effects Dr J. M. Marsden-Davies in to whom we owe this lecture in a paper devoted to the pioneer of British radiology, Dr J. H. Poynton, Society a simple method of enclosing the worker in a wooden box very thick coated with a mixture of red and white lead with a suitable opening for the eyes of the x-ray worker, made east of Paris in 1904. This led to the use of the tube which was used for the purpose of shielding the operator. But it was not until 1911 that this step of systematic and formal protection was taken on the vital subject of protection of x-ray workers were taken.

The long list of deaths and mutilations among the pioneers of medical radiology is a painful reminder of the notice by a succession of deaths from the same cause. It was then that Dr J. H. Poynton, who died on March 25th 1921. As a result of this, the British Association of Radiologists was formed. It is obvious that the one authoritative authority on the practice of radiology was for the time being in this branch of the profession was not to be regarded as needed but overdue. Accordingly there was set up in 1921 a committee containing physics and radiology.

nominated by the National Physical Laboratory, the Röntgen Society, which exists in the war (in 1915) devised methods of protection, the Electro-therapeutic Section of the Royal Society of Medicine, the British Association for the Advancement of Radiology and Physiotherapy (now the British Institute of Radiology), the Institute of Physics, and the Radium Institute of London, with a representative of the manufacturers' interests, and Professor S. Russ and Dr. Stanley Melville as honorary secretaries. It appeared desirable that the members of the committee should all be resident in London, as the urgency of the matter necessitated frequent and prolonged meetings, and it was therefore reluctantly felt that it would be hardly possible to ask radiologists in the country to make the necessary sacrifice. No time was indeed lost, for the committee issued its recommendations in July, 1921, and after a second revised report in December, 1923, when the amount of preliminary discussion had become much less exacting, the members co-opted three leading radiologists from Edinburgh, Manchester, and Liverpool, in order to strengthen their hands. A third and expanded report, containing a section on ultra-violet therapy, is now in the press. It is not generally known how much radiologists owe to the National Physical Laboratory and the Röntgen Society for the help and the funds necessary for printing and distributing these reports, several thousand copies of which have been sent out to hospitals all over the United Kingdom. Arrangements were made whereby, when requested, experts from the National Physical Laboratory inspected x-ray departments to report whether the protection provided conformed to the recommendations of the committee. After some not unnatural hesitation, as this country was the first to insist on the need for such protective measures, British manufacturers adopted the recommendations, and their reception has been generally satisfactory, thus the early changes in the blood have been shown to be prevented by the adoption of protective precautions. The Ministries of Health and of Pensions in this country have given their support, and other countries, such as the United States of America, Norway, Holland, and Russia have issued recommendations following fairly closely the lines laid down by the committee. It is desirable, as Kray has urged, that international agreement, at any rate on the main questions of protective measures, should be secured. On February 1st, 1924, the Home Secretary issued an order extending the scope of the Workmen's Compensation Act, 1906, to include radio-dermatitis, which thus becomes one of the industrial diseases scheduled as entitling to compensation.

This has naturally been some criticism of these recommendations—for example, by Gloeker and Altschul—but it is noteworthy that this has been directed to show that the protection recommended errs on the side of excess and not of omission, thus it has been asserted that some of the regulations, though they may apply to large busy x-ray departments, are much more than is necessary in the departments of small hospitals, and that the amount of protection as measured in millimetres of lead is not only cumbersome but excessive in the experience of some well known radiologists. In answer to these objections it may be said that the recommendations are directed to render the practice of radiology safe for all those so engaged, and that any system of "graded" protection, for use in x-ray departments of different activities, would, as pointed out by Kray, be difficult and open to the risk of misinterpretation and so favour the occurrence of the evil effects which the recommendations are designed to prevent. An important reason for the maintenance of a high standard of protection is that the use of x-ray installations is far from being entirely in the hands of experts and medical men. The ever-extending use of x-rays will entail installations of special characters in factories and industrial workshops and it is obviously important to leave no loophole whereby the employees may eventually be seriously damaged.

As there is not yet any agreed standard unit of x-ray intensity that can be safely borne by everyone, it has been necessary to calculate the protective thickness of lead so as to cut off all the rays. In other words, the recommendations are worked out from the physical point of view so as to ensure complete protection from irradiations and

not from the biological and clinical standpoint of limiting the amount of irradiation to what can safely be borne by the average individual. As yet there is not any international standard x-ray unit, though an International X-Ray Unit Committee, with representatives from seventeen countries set up at the International Congress of 1925, is at work on it. The question of the measurement of the dose of radiations has recently been reviewed with a full bibliography by Gunsett, and Mutscheller has tried to devise formulae to establish physical standards of protection against the dangers of x-rays whereby the average safe dose of radiations to which an x-ray worker may be constantly exposed can be calculated, but even if the quantity of x-rays expressed in terms of the unit skin dose, which experience shows can be safely tolerated for years by some radiologists, could be satisfactorily determined, there is still the question of idiosyncrasy and acquired supersensitiveness to be taken into account. It is important that the recommendations for protection should be based on the principle of absolute safety first, and err, if they do so at all, on the side of excess, so that, as Melville argues, the life of an x-ray worker should, from an assurance point of view, be a perfectly suitable risk.

### *Idiosyncrasy*

Although in the early days of x-ray work the radiations were weak as compared with those now available from the Coolidge tube, many of the pioneers suffered severely, while others, although they did not take any further precautions, escaped. The much discussed question of personal idiosyncrasy to radiations has been imprudently considered by Colwell and Russ, who quote the answers to Arcelin's questionnaire among radiologists of repute seven believed in its existence and six took the opposite view. Mackee, who defines idiosyncrasy as a severe reaction to a very small dose—one-quarter to one-sixteenth of the unit skin dose—considers it very rare, as he has not seen an example in twenty years' work. The opinion of Dr. A. E. Barclay and Mr. Henry Pinch, which I am allowed to quote, is to the effect that extreme supersensitiveness is rare, and that the real explanation of many reputed examples is undue exposure or faulty technique.

Speaking generally, idiosyncrasy may be congenital or acquired, and may be supersensitiveness, which is that usually implied, or in the reverse direction—namely, insensitiveness. While radiations of sufficient strength and dose will produce reactions in everyone, there is considerable variation in the susceptibility of different persons. Those with light hair and a fair skin give reaction more readily than brunettes—no doubt from the small amount of protective pigment in the skin. According to David, a normal person gives a distinct x-ray erythema, whereas some individuals, probably from a different constitution depending on endocrine influence, give quite a different pathological reaction. Mackee and Eller tested 220 persons with 1/4, 1/2, and 3/4 of the unit dose of x-rays, and found that 11, or 5 per cent, developed erythema with 1/4, 31, or 14 per cent, with 1/2, and 54, or 25 per cent, with 3/4 of the unit dose. It would appear to be impossible to deny the occurrence of an inborn supersensitiveness to radiations, though extreme degrees may be very unusual.

*Acquired supersensitiveness* to radiations is well recognized in the case of the skin, and T. Lewis has shown that damage of the blood vessels by x-rays leaves them in a curious condition of inability to respond to vasoconstrictor stimuli, this has been ascribed to injury to the Rouget cells. The occurrence of post-radiation telangiectases usually within two years, but sometimes longer delayed, even to fifteen years, is well known. They are probably always preceded by an erythema, which, however, may be very slight. The same individual may react differently at different times, Mottram (1924) has shown that an increased blood supply, such as is caused by heat, sunburn, or other factors, makes the skin more prone to react to radium, and, according to Knox, this may be due to secondary irradiations in the iron of the haemoglobin.

Supersensitiveness developing after exposure to radiations has been described both in patients and radiologists. M. and G. Giraud and Pares recorded a case of myeloid leukaemia in which, after tolerance for the long period

In even a brief discussion the serological aspect cannot be omitted. The spinal fluid picture which we have found to be almost constant is a normal or slightly increased cell count, a normal protein content, a negative Wassermann reaction, and a positive reaction to colloidal gold.<sup>15</sup> This latter test, in conjunction with a negative Wassermann reaction, is, in my opinion, of undoubted value in the recognition of early cases of the disease.

### Symptomatology

As regards the symptomatology of disseminated sclerosis, I would like to emphasize one of the earlier manifestations. Retrobulbar neuritis is specially worthy of investigation and experimental research. In one of my cases of frank disseminated sclerosis in a woman aged 37 I obtained the following history. Fifteen years prior to the onset of gross symptoms she had suffered for a short time from bilateral retrobulbar neuritis, but in the interval had appeared to be in good health. Here we would appear to have a latency of infection comparable with syphilis. The occurrence of so-called idiopathic retrobulbar neuritis in a young and otherwise healthy adult should always be carefully investigated as a potential early manifestation of disseminated sclerosis.

### Occupational Incidence

So far I have referred chiefly to laboratory methods in the investigation of this disease. There are other channels into which inquiry may be profitably directed. It is of great importance not merely to study the natural history of a disease, but especially to investigate the circumstances under which the earliest manifestations appeared. The following observations are based on my personal experience of cases in the West of Scotland, and may be governed by conditions peculiar to the district. The majority of the patients I have seen with disseminated sclerosis come from the country, as opposed to the town. The incidence of the disease in this respect would appear to be in direct contrast to that of neuro-syphilis. The typical picture is that of a young adult, usually of good physique and with a healthy family history. It is excessively rare to find two cases occurring in the same family or in the same household—a fact which would point either to special personal susceptibility or to special exposure to infection. In this connexion the theory of insect transmission is worthy of investigation. Such a view has already received the support of Dreyfus<sup>16</sup> in a published paper and Kuhn in a personal conversation. The occupations which seem to me to render the individual most liable to infection are farming, woodworking, game-keeping, gardening, bye-keeping, etc. Persons so employed are essentially earning their living in the open air in country districts. It is not only in these individuals that the disease seems specially liable to occur, but also in various members of their families. Recently McAlpin<sup>17</sup> has referred to the desirability of investigating this occupational incidence of the disease.

Admittedly such a history cannot be obtained in a proportion of cases, but when one realizes the apparent latency of infection, to which reference has already been made, the difficulties of ascertaining when and where the infection occurred will be immediately apparent.

3530, 3531, 3532, 3533, 3534, 3535, 3536, 3537, 3538, 3539, 3540, 3541, 3542, 3543, 3544, 3545, 3546, 3547, 3548, 3549, 3550, 3551, 3552, 3553, 3554, 3555, 3556, 3557, 3558, 3559, 3560, 3561, 3562, 3563, 3564, 3565, 3566, 3567, 3568, 3569, 3570, 3571, 3572, 3573, 3574, 3575, 3576, 3577, 3578, 3579, 3580, 3581, 3582, 3583, 3584, 3585, 3586, 3587, 3588, 3589, 3590, 3591, 3592, 3593, 3594, 3595, 3596, 3597, 3598, 3599, 3600, 3601, 3602, 3603, 3604, 3605, 3606, 3607, 3608, 3609, 3610, 3611, 3612, 3613, 3614, 3615, 3616, 3617, 3618, 3619, 3620, 3621, 3622, 3623, 3624, 3625, 3626, 3627, 3628, 3629, 3630, 3631, 3632, 3633, 3634, 3635, 3636, 3637, 3638, 3639, 3640, 3641, 3642, 3643, 3644, 3645, 3646, 3647, 3648, 3649, 3650, 3651, 3652, 3653, 3654, 3655, 3656, 3657, 3658, 3659, 3660, 3661, 3662, 3663, 3664, 3665, 3666, 3667, 3668, 3669, 3670, 3671, 3672, 3673, 3674, 3675, 3676, 3677, 3678, 3679, 3680, 3681, 3682, 3683, 3684, 3685, 3686, 3687, 3688, 3689, 3690, 3691, 3692, 3693, 3694, 3695, 3696, 3697, 3698, 3699, 3700, 3701, 3702, 3703, 3704, 3

suprarenal gland. It would also seem possible that this sympathetic autonomy may account for some of the many symptoms such as headache and sensations of tingling and numbness in the extremities, which make up the menopausal syndrome.

#### The Use of Thyroid Extract at the Menopause

Thyroid extract is frequently used at the menopause. As I have shown elsewhere (3), the intensity of the attacks of flushing at the menopause is increased by the administration of thyroid extract at this time. This phenomenon is to be expected if, as has been suggested by Cotsch, the internal secretion of the thyroid gland sensitizes the body cells to the action of adrenaline.

In my opinion therefore thyroid extract should not be given as a routine, to women at the menopause.

#### The Use of Chloroform as an Anesthetic at the Menopause

There is considerable evidence that the syncope which occurs during the induction of chloroform anaesthesia is associated with fibrillation of the cardiac ventricles and is caused by abnormal irritability of the heart muscle in which the sympathetic nerve supply is involved. Cushman says that this ventricular fibrillation is possible caused by reflexes through the accelerator apparatus, or by an increased action of the suprarenal gland. If as I have shown women at the menopause are sympathetotonic chloroform should be avoided as an anesthetic at this time.

Following a suggestion made to me by Dr W. F. Dixon I have endeavored to ascertain if women at the menopause are particularly susceptible to chloroform syncope owing to the infrequency with which chloroform is administered in these days and the comparatively few cases of chloroform syncope which have been recorded with details of the

menstrual history at the time of the accident. My researches into this question have hitherto been unsatisfactory. It is interesting however to remember that pregnant women in whom the ovaries are present in a condition of increased activity are extremely tolerant to chloroform.

The preparation of the active hormone or hormones of the ovary is attended with many technical difficulties, and I know of no satisfactory product at present on the market. I am satisfied however that some of the ovarian extracts which are available are effective to a limited and varying extent but until an active substance, or standard preparation, is available the clinical value of these preparations must remain inconclusive.

#### Summary

1. The tonus of the sympathetic nervous system of women at the menopause is increased.
2. The increase in tonus of the sympathetic nervous system is responsible for the vasomotor phenomenon and possibly for some of the other symptoms which make up the menopausal syndrome.
3. The increase in tonus of the sympathetic nervous system at the menopause is caused by the arrestation of action of the suprarenal gland, the internal secretion of the ovaries being deficient or absent.
4. Thyroid extract should not be administered to the menopause owing to its adrenal sensitizing action.
5. Chloroform should not be used as an anesthetic in women at the menopause.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL

#### RUPTURE OF THE HEART

An edentulous man aged 71 was given a large cup of hot meat extract at 11 p.m. followed an hour later by a large cup of hot cocoa. He was found dead in bed at 1 a.m. At the post-mortem examination I found a rupture 1 in long in the anterior wall of the left ventricle. The muscle was pale flabby, and fibrotic. The stomach was enormously distended with air. I concluded that in stopping the hot liquid he had swallowed this air and the consequent distension of the stomach embarrassed the heart sufficiently to tear it.

In the interesting paper by Drs Strickland Goodall and Wen (May 7th p. 834) there is a history of recently ingested food or fluid in seven out of fourteen cases. One would like to know the condition of the stomach in the cases and whether flatulent distension was a contributory factor to the rupture.

H. STANLEY CHATE, M.B.

#### HEPATIC DEFORMITY OF THE FINGERS

A man, aged 22, presenting the following abnormality of the fingers was admitted to Addenbrooke's Hospital in November 1926, suffering from renal calculus.

The middle and terminal phalange were shortened the fingers being of the average breadth for an adult man. The base of each finger-nail is double. The two parts are separated by almost normal skin which runs distally over the dorsum of the terminal phalanx and continuous with the skin covering the tip of the finger. On either side of this medially a strip of skin nail tissue appears of the normal texture and elasticity. The cuticle is present on each side and overlaps the nails in the usual fashion. The intermediate central part is harder than normal skin and bears longitudinal striations, it is, however quite distinct from the nails. At the distal end there is the usual shallow transverse groove, where the free end of the nail should be. The little finger of the left hand approaches the nearest to

normal. There is here a nail occupying three-fifths of the width of a normal nail. The man used to scratch his finger when a boy in order to make the nail grow.

The thumbs show this peculiarity in the highest degree. The nail bed on each side is represented by a 2 mm width and 4 mm in length each containing a tiny nail. The nail all grows over and seldom require cutting. The feet are normal.

The man stated that several members of his family have hands similar to his own. In the following table the persons marked with a cross are those who exhibit this deformity.

In even a brief discussion the serological aspect cannot be omitted. The spinal fluid picture which we have found to be almost constant is a normal or slightly increased cell count, a normal protein content, a negative Wassermann reaction, and a positive reaction to colloidal gold.<sup>15</sup> This latter test, in conjunction with a negative Wassermann reaction, is, in my opinion, of undoubted value in the recognition of early cases of the disease.

### Symptomatology

As regards the symptomatology of disseminated sclerosis, I would like to emphasize one of the earlier manifestations. Retiobulbar neuritis is specially worthy of investigation and experimental research. In one of my cases of frank disseminated sclerosis in a woman aged 37 I obtained the following history. Fifteen years prior to the onset of gross symptoms she had suffered for a short time from bilateral retiobulbar neuritis, but in the interval had appeared to be in good health. Here we would appear to have a latency of infection comparable with syphilis. The occurrence of so called idiopathic retiobulbar neuritis in a young and otherwise healthy adult should always be carefully investigated as a potential early manifestation of disseminated sclerosis.

### Occupational Incidence

So far I have referred chiefly to laboratory methods in the investigation of this disease. There are other channels into which inquiry may be profitably directed. It is of great importance not merely to study the natural history of a disease, but especially to investigate the circumstances under which the earliest manifestations appeared. The following observations are based on my personal experience of cases in the West of Scotland, and may be governed by conditions peculiar to the district. The majority of the patients I have seen with disseminated sclerosis come from the country, as opposed to the town. The incidence of the disease in this respect would appear to be in direct contrast to that of neuro-syphilis. The typical picture is that of a young adult, usually of good physique and with a healthy family history. It is excessively rare to find two cases occurring in the same family or in the same household—a fact which would point either to special personal susceptibility or to special exposure to infection. In this connexion the theory of insect transmission is worthy of investigation. Such a view has already received the support of Dreyfus<sup>16</sup> in a published paper and Kuln in a personal conversation. The occupations which seem to me to render the individual most liable to infection are farming, woodworking, game-keeping, gardening, bare-keeping, etc. Persons so employed are essentially earning their living in the open air in country districts. It is not only in these individuals that the disease seems specially liable to occur, but also in various members of their families. Recently McAlpine<sup>17</sup> has referred to the desirability of investigating this occupational incidence of the disease.

Admittedly such a history cannot be obtained in a proportion of cases, but when one realizes the apparent latency of infection, to which reference has already been made, the difficulties of ascertaining when and where the infection occurred will be immediately apparent.

## ON CERTAIN ADRENALINE EFFECTS AT THE MENOPAUSE AND THEIR SIGNIFICANCE

(Preliminary Communication)

By

JOHN H. HANNAN, M.A., M.D., B.Chir Cantab,  
LONDON

In two theses read by myself at Cambridge dealing with the causation and treatment of "flushing" at the menopause, and in a recently published monograph on the same subject (1), I have drawn attention to certain adrenaline effects observed during my researches.

### Flushing Produced by Adrenaline

Intravenous injections of 10 minims of a 1 in 1,000 solution of adrenaline chloride, in women complaining of flushing at the menopause, gave rise, in all cases, to an immediate attack of flushing which was in all respects identical with the attacks which occurred spontaneously.

In order to exclude the possibility of this experimental flushing being caused by an increase in blood pressure, or the painful stimulus of an injection, control injections were made of pituitin and normal saline, in no instance did the control injections give rise to an attack of flushing. It would appear, therefore, that the production of flushing at the menopause by the intravenous injection of adrenaline is due to the specific action of this substance.

A consideration of the results obtained by observers, such as Petzetakis, on the effects of intravenous injections of adrenaline in normal individuals yields no evidence of the production of flushing by adrenaline in such individuals.

### Increased Tonus at the Menopause

Loewi's reaction—namely, dilatation of the pupil following instillation of adrenaline into the conjunctival sac—occurred in 40 per cent of those women at the menopause upon whom the experiment was tried, the reaction was constant on eight consecutive days, only women who complained of flushing were selected for this experiment.

If adrenaline be instilled into the conjunctival sac of a normal individual no dilatation of the pupil occurs, owing to the destruction of the adrenaline (Dixon). In some diseases of the pancreas, however, where there is impairment of the secretory cells, certain adrenaline effects become more pronounced and dilatation of the pupil occurs, this phenomenon being caused, according to Loewi, by the absence of the restraining influence of the pancreas on the suprarenal glands, these glands being physiological antagonists. Bearing in mind, therefore, that pancreatic disease might be present in some of my cases, an examination of the urine was undertaken in those cases where the pupil reaction was positive, in no instance was evidence of glycosuria obtainable.

From my experiments it would appear that the sympathetic nervous system of women, who at the menopause complain of flushing, is in a condition of increased tonus. The menopause is, we know, associated with ovarian atrophy and loss of the Graafian follicles, furthermore, removal of both ovaries will produce a syndrome closely resembling the natural process. My research, therefore, would seem to indicate that the internal secretion of the ovaries and that of the suprarenal glands (medullary portion) are physiological antagonists.

The ovarian extracts which are available at the present time are unsatisfactory, but I have had some success in the treatment of flushing at the menopause by the subcutaneous administration of an extract of the whole ovary in combination with a dry extract of the corpus luteum, or, (2) in two of my cases, Loewi's pupil reaction has disappeared under ovarian substitut on therapy.

### The Significance of Adrenal Sensitiveness at the Menopause

It would appear from my research that the flushings of the menopause are due to an increase in the tonus of the sympathetic nervous system at this time, this increase being caused by the absence of or deficiency in the restraining influence of the internal secretion of the ovaries on the

suprarenal glands. It would also seem possible that this sympatheticism may account for some of the many symptoms such as headache and sensations of tingling and numbness in the extremities, which make up the menopausal syndrome.

#### The use of Thyroid Extract at the Menopause

Thyroid extract is frequently used at the menopause. As I have shown elsewhere (3), the intensity of the attacks of flushing at the menopause is increased by the administration of thyroid extract at this time. This phenomenon is to be expected if, as has been suggested by Coetsch, the internal secretion of the thyroid gland sensitizes the body cells to the action of adrenaline.

In my opinion, therefore, thyroid extract should not be given as a routine, to women at the menopause.

#### The Use of Chloroform as an Anaesthetic of the Menopause

There is considerable evidence that the syncope which occurs during the induction of chloroform anaesthesia is associated with fibrillation of the cardiac ventricle and is caused by abnormal irritability of the heart muscle, in which the sympathetic nerve supply is involved. Cushman says that this ventricular fibrillation is possibly caused by reflexes through the accelerator apparatus, or by an increased secretion of the suprarenal gland. If as I have shown women at the menopause are sympathetotonic, chloroform should be avoided as an anaesthetic at this time.

Following a suggestion made to me by Dr W. E. Dixon, I have endeavoured to ascertain if women at the menopause are particularly susceptible to chloroform syncope, owing to the infrequency with which chloroform is administered in these days, and the comparatively few cases of chloroform syncope which have been recorded with details of the

menstrual history at the time of the accident, my researches into this question have hitherto been unsatisfactory. It is interesting, however, to remember that pregnant women, in whom the ovaries are present in a condition of increased activity, are extremely tolerant to chloroform.

The preparation of the active hormone or hormones of the ovary is attended with many technical difficulties and I know of no satisfactory product at present on the market. I am satisfied, however, that some of the ovarian extracts, which are available are effective to a limited and varying extent, but until an active substance of standardized potency is available the clinical value of my observations must remain inconclusive.

#### Summary

- 1 The tones of the sympathetic nervous system at women at the menopause is increased.
- 2 The increase in tone of the sympathetic nervous system is responsible for the vasomotor phenomena and, possibly for some of the other symptoms which make up the menopausal syndrome.
- 3 The increase in tone of the sympathetic nervous system at the menopause is caused by the internal secretion of the suprarenal glands, the internal secretion of the ovaries being deficient or absent.
- 4 Thyroid extract should not be administered at the menopause owing to its adrenal sensitizing action.
- 5 Chloroform should not be used as an anaesthetic in women at the menopause.

#### HEREDITARY DEFORMITY OF THE FINGERS

A MAN aged 22 presenting the following abnormality of the fingers was admitted to Addenbrooke's Hospital in November 1926 suffering from renal calculus.

The middle and terminal phalanges are shortened, the fingers being of the average breadth for an adult man. The base of each finger-nail is double. The two parts are separated by almost normal skin which runs distally over the dorsum of the terminal phalanx and is continuous with the skin covering the tip of the finger. On either side of this medially a strip of skin nail tissue appears of the normal texture and elasticity. The cuticle is present on each side and overlaps the nails in the usual fashion. The intermediate central part is broader than normal skin and bears longitudinal striations, it is, however, quite distinct from the nails. At the distal end there is the usual shallow transverse groove where the free end of the nail should be. The little finger of the left hand approaches the nearest to

normal. There is here a nail occupying three-fifths of the width of a normal nail. The man used to scratch the finger when a boy in order to make the nail grow.

The thumb's show this peculiarity in the highest degree. The nail bed on each side is represented by area 2 mm. in width and 4 mm. in length, each containing a tiny nail. The nails all grow slowly and seldom require cutting. The feet are normal.

The man stated that several members of his family have hands similar to his own. In the following table the persons marked with a cross are those who exhibit this deformity.

The patient could not trace his family further back than the grandfather, nor could he state whether the abnormality had ever been transmitted through one of the female members of the family.

I am indebted to Dr J. Alden Wright for permission to publish details of this case.

NOEL CHILTON, B.A., B.M., B.Ch.  
Late House Physician Addenbrooke's Hospital, Cambridge.  
Surrey.

#### AN UNRECOGNIZED CASE OF FRACTURE OF A CERVICAL VERTEBRA

The following case presents some points which may be of interest.

A man aged 33 was admitted to the Chester Infirmary in May 1926 during the general strike after being run over by a railway lorry which crushed his chest. No fracture of the ribs could be found, and as he had apparently quite recovered, he was discharged after a short stay in hospital.

wrote prior to operation on his frontal sinuses suffice to demonstrate his delusional insanity. And he been satisfied as means it would have been a matter of great difficulty for him to regain the confidence of his bank directors.

(c) Bacteriological examination of the nasal sinus contents demonstrated pure culture of *Staphylococcus aureus*, so often regarded as of little import. Teeth and tonsils were not involved, his previous appendicectomy had apparently removed the only other involved focus of infection, making his a pure nasal infection case.

Let me refer very briefly to one example at the other extreme—the very mild type of chronic nasal sepsis.

A man, aged 56 complained of deafness with post nasal catarrh, never severe, but of twenty-seven years' duration. He had been tired off and on during that long period, but latterly had been getting depressed, lessened mental acuity causing difficulty in carrying on his work, he complained also of general muscular weakness. Exploration of his nasal sinuses revealed no obvious pus, but Dr Todd, who examined the extracted contents found, together with polymorphonuclears, streptococci and Friedländer's pneumobacillus in the right sphenoidal and posterior ethmoidal cells, the other sinuses being sterile. The infected sinuses were opened and drained and he soon felt stronger, increased in weight, and, as he put it, brighter than he had ever done for years past.

It is certainly not intended to suggest that all patients whose tonsils, sinuses, ears, or teeth are mildly infected must be operated on, or that they are the subject of functional psychoses, any more than is the individual who is somewhat melancholic because his liver is sluggish or he is constipated. Few individuals are there who, in the course of common colds or influenzal attacks and so forth, have not been the subject of transient nasal sinusitis, fortunately the great majority of such infections clear up spontaneously by auto-immunization, or with the appropriate measures of ordinary medication, while every medical practitioner knows that rest, feeding up, change of air, and so on are very often all that is required to obtain complete cure.

It is cases of chronic sepsis with mental depression and neurasthenic symptoms which do not yield to ordinary medicinal measures, or that seem to clear up only to recur, that we need to recognize, and to associate the functional psychosis with the physical abnormalities that may be the underlying and removable cause.

It is necessary to emphasize the "latent" or hidden character of the focal sepsis in many patients who nevertheless are the worst sufferers from chronic toxicæmia. First, there is often an absence of pain or other symptoms directing attention to the real source of infection, and, secondly, it is significant that patients with chronic copious purulent discharge but seldom suffer from toxicæmic symptoms as compared with those with little discharge, and that often non-purulent to the naked eye. Many years ago I suggested

that in the numerous polymyositis in the one case, as contrasted with the purity of polymyositis in the others, we have an explanation of the remarkable differentiation to which I have drawn attention.<sup>1</sup> Subsequent experiences have borne out the truth of this, and in the latent character of apical dental sepsis, which often enough can only be detected by radiograms, we have a further exemplification of the cryptogenic character of some of the most potent sources of focal sepsis.

If it be recognized that owing to the existence of focal sepsis a considerable percentage of patients are miserable, the subject of neurasthenia or of functional psychosis of grave character, rendering their lives more or less useless to themselves or a source of danger to the community, it is hardly necessary to urge the duty of ferreting out these septic foci—which involves regard to the gastro-intestinal tract (for example, for evidence of colitis, enteric ulceration, appendicular infection), to the genito-urinary tract, the teeth, fauces, nasal sinuses, the ear, and so forth.

In such investigations we must often invoke the aid of radiology, of analysis of gastric contents and of the feces. How many asylums to day have such essential resources at their disposal? Yet within a few years I believe that with each one will be actively associated a consulting physician, surgeon, dentist, radiologist, laryngologist, and pathologist. Let us cast no stones, for hitherto we as a profession have barely recognized the symptoms which should call for the elimination of focal sepsis as the *fons et origo* of some patients' afflictions in whom the ostensible diseases are

merely the end results. Of this we may feel assured—sepsis is a far deadlier foe to civilized races than tuberculosis.

## ON AURAL FOCAL SEPSIS AS A SOURCE OF NEURASTHENIA AND INSANITY

BY

P. WATSON-WILLIAMS, M.C., CH.M.,

CLINICAL LECTURER IN LARYNGOLOGY AND OTOTOLOGY IN THE  
UNIVERSITY OF EDINBURGH

It has long been recognized that disease of the ear may lead to mental disturbance more or less severe. Even so simple a matter as removing a plug of wax has been recorded to have cut short an attack of mania. As regards aural suppuration, attention in the past appears to have been directed in this connection to deafness, tinnitus, pain, vertigo, and intracranial complications. In short, only disease of the organ of hearing, and local complications, seem to have been considered. With such I am not here immediately concerned.

Many instances of the association of one or more of these conditions with mental trouble have been recorded. Tinnitus especially is noteworthy, some writers even go so far as to say that most cases with hallucinations of hearing ought to be classed as suffering from delusions, there being some definite aural lesion to account for their symptoms. Vertigo is well known to induce definite neurasthenia in some cases. We ought to be careful that disinclination to mix in traffic, or a shivering from work, say, as a stoker, or on a scaffolding, is not incorrectly ascribed to neurasthenia, when really due to laudable prudence. I have had the good fortune to see both this false neurasthenia and a true neurasthenia disappear when suitable treatment has relieved the vertigo. A few cases of intracranial abscess have been published where treatment has relieved a definite psychosis, but too many of the records showing this association are from autopsies, no treatment having been instituted. I may summarize the situation by recalling the plea of Forrester<sup>1</sup> which, in 1901, he added to a record of a case successfully treated—that every patient suffering from mental change should have the ears examined. In the same year Dr. Bernard Hollander wrote

By these cases one is forcibly taught the lesson that an apparently slight and unimportant ailment such as a running from the ear, which is apt to be looked upon as an inconvenience rather than a disease, may prove very dangerous.

### TOXÆMIA

Putting aside these local manifestations, I shall omit all cases in which tinnitus, vertigo, or intracranial complications were known to be present, and all cases in which there was not a family history free from mental taint, and shall confine myself to those instances in which surgical treatment of aural sepsis brought relief from the mental symptoms.

Towards the close of last century much attention seems to have been directed to the question whether toxicæmia was a factor of importance in the causation of insanity. Among the records of many discussions, perhaps the most interesting is that at the Medical Society of London on May 11th, 1896, opened by Dr. A. M. Hamilton of New York, on "The connexion of autotoxæmia with certain forms of insanity." The idea that chronic septic absorption could

produce "toxæmia" was not, however, then current, the word was applied rather to poisoning from the presence in the circulation of products of abnormal metabolism, or the result of intestinal stasis. It is not surprising, therefore, that at that time little attention appears to have been given to the middle ear tract as a possible source of chronic toxæmia. But it is now over fifteen years since West and Scott<sup>3</sup> pointed out this possible complication. It seems noteworthy that even now the possibility is in some danger of neglect.

#### NEURASTHENIA

Perhaps for this reason the evidence I shall put forward is less complete than its importance deserves. It is not common in aural practice to find cases of definite insanity. Far more usual is it to see patients with minor disturbances, such as are usually described as neurasthenia. It is remarkable how regularly the same group of mental symptoms occurs in all descriptions of toxæmia, whether considered from a general or a local aspect. There is a sort of mental lassitude, the victim finds that the effort demanded by social duties is becoming too great, work which formerly he performed with ease and pleasure has become laborious, when he forces himself to work, he cannot concentrate his mind, he feels he has lost his initiative, memory may fail or more typically become "patchy", and to make a decision even on some quite minor matter involves a disproportionate effort.

A sufferer from such a condition came to me two years ago. He told me nothing of his trouble, but sought advice for a running ear. I carried out a radical mastoid operation for purely local conditions. Some months later he came to tell me of his neurasthenia, which all his friends had noted. After the operation the whole of the train of symptoms which were practically identical with the series I have indicated above, completely disappeared.

Another case was that of a chef. He had had to give up his work and though he had been trained in a less strenuous occupation he found this also was too great a strain. There was some physical evidence of toxæmia but the most marked feature was his depression and hopelessness. A short fortnight after the operation on his ear—which was performed mainly on account of the general condition—the change in his whole bearing was remarkable. He became bright and cheerful, got work at a big hotel as head chef and has been hard at it ever since—a matter of three years.

#### EPILEPSY

For statistical information on the association of ear disease with epilepsy I would refer to a paper by Dr Omerod.<sup>4</sup> He found an incidence of epileptic fits several times greater in the subjects of otorrhoea than in the hospital population generally. I will cite a case in my own practice.

A man of middle age came to me for otorrhoea of old standing rather profuse and associated with some pain but not much. He was also subject to fits described by his doctor as epileptiform. While other treatment was being tried for the ear, the fits became more frequent—one or two every week. I therefore operated on an extensively diseased mastoid. This was only ten weeks ago but he has had no fits since the operation, and the outlook is distinctly promising.

#### INSANITY

Undoubtedly the most dramatic and convincing cases are those in which definite mental derangement has yielded to surgical treatment. The earliest case that I have found to illustrate my thesis is reported by L. Merz.<sup>5</sup> In this definite association of mental disease with otorrhoea was noted before operation on a chronic mastoid abscess resulted in restoration to mental health. Nearly fifty years ago Dr W. Rhys Williams recorded a very striking case.<sup>6</sup>

A man aged 26 married family history, negative general health good, always industrious and sober. Thirteen days before admission to Bethlem he became depressed and rambling in his speech. Then he became excited, violent and incoherent. He had delusions: (1) that he was firing rockets at Edinburgh Castle; (2) of seeing devils; (3) of persecution by electricity. No aural symptoms were noted but he was noisy and sleepless. After admission he was sullen and quiet but a fortnight later he was again raving. Ten months after a discharge was noticed from the left ear. He stated that he had had this for a long time. Mastoid tenderness and swelling were observed, and a chronic abscess of the Bezold type was treated three operations being performed and 'he became sane at once'. Shortly after he was discharged cured.

I showed at the meeting of this Branch in January last a man who had had mild otorrhoea very chronic with no serious local symptoms. He had been comfortable under palliative treatment

for some months. But somnambulism with a habit of lighting fires and even more serious derangements of conduct developed and it appeared that he was going to become certifiably insane. I performed a radical mastoid operation with the happy result of completely relieving his mental condition and he remains well and is at work.

#### SUMMARY

What deductions are we to draw from these cases? It will not be disputed that an examination of the ears should be a part of the routine examination of every subject of mental disease. But even where there appears no local condition calling for surgical treatment, if we suspect that focal sepsis is at the bottom of the trouble, we must not forget the ears when seeking a possible source of that trouble. This is not less important when dealing with cases of milder mental disturbance, for the patient may think the running ear of little moment and omit to mention it, but such cases seem to yield comparatively readily to treatment. Finally, when considering the question of operative treatment of otorrhoea, we must have in mind the possible effects on the general health, mental as well as physical, of septic absorption from this source.

## FOCAL SEPSIS AS A FACTOR IN THE CAUSATION OF NEURASTHENIA AND INSANITY

BY

J. A. NIXON, C.M.G., M.D., F.R.C.P.,  
PROFESSOR OF MEDICINE, UNIVERSITY OF EXETER

This question of mental disturbances from focal sepsis is most important, but sufficient attention has not been given to it in the past. It serves to emphasize the absolute necessity for a most scrupulous examination of every patient suffering from neurasthenia or graver mental trouble. This is, indeed, only fair, for there might be found some definite lesion to account for what had been thought an hallucination. In one case, it was alleged as a sign of insanity that the patient said he had a cannon-ball in his chest, this man was found, on x-ray examination, to have a large and unsuspected aneurysm.<sup>1</sup> Further, it is remarkable what gross damage may exist with apparently little mental change; it is necessary to be on guard that a serious intracranial lesion is not overlooked.

In considering the mental changes associated with focal sepsis, I might instance for comparison the well known mental disturbances associated with the onset of infective fevers such as typhoid or pneumonia. If an acute infection could so much disturb the mentality in a few hours, it should cause no surprise that a chronic toxæmia could produce insanity in the course of months. I propose, however, to leave out of account the acute fevers, as not being within the scope of "focal sepsis."

The cases in which chronic septic absorption appears to be a definite factor in causing mental disturbance are of the greatest interest and importance. I will relate one or two that have come within my own observation.

**Case 1**—Just before the war I was called to see a young professional man who had attempted to commit suicide. The family history was exceedingly bad and it was at first thought that the prospect of mental recovery was poor. An alienist called in consultation took a different view. He observed that the periods of depression to which the patient was subject coincided with attacks of constipation so severe as to be absolute for eight or ten days together and he was strongly opposed to the man becoming an inmate of an asylum even as a voluntary boarder. Advice was given as to the proper regulation of the bowels, and the patient was put in the care of friends. He completely recovered and has been since 1916 an active and hard working man.

**Case 2**—A woman was admitted to hospital with acute mania. Observation showed that she had always a slight daily rise of temperature. Further investigation revealed infection by *B. coli* of the urinary tract. Under treatment this was relieved and simultaneously the mental state became normal.

**Case 3**—A working quarrryman, a man of poor education became during the war the owner of a quarry and the possessor of considerable wealth. He began to suffer from delusions and

melancholia and was soon quite insane. It seemed clear that his altered circumstances and the responsibilities of ownership and management had brought about his downfall. He had, however, a very septic mouth; extraction of all his teeth was followed by complete restoration to mental health.

*Case 4*—In this instance a man had no fewer than three sources of septic absorption: he suffered from chronic nasal sinus disease, from dental sepsis, and from chronic appendicitis. The mental state was one of extreme introspection, with definite suicidal tendencies. Surgical treatment of all three foci has been carried out. It is six weeks only since this was completed. He says he is 'a new man'. Although the history is so recent, it is full of promise.

I think it probable that most of the cases of puerperal mania are septic in origin—perhaps the actual focus of infection is small and the grade of infection low. The important point seems to be that, if in a given case of mental disease we can find the cause, and eliminate it, we shall be able to give a good prognosis. This good prognosis we are accustomed to give for example in cases of post-typhoid insanity, because we recognize that the toxic state does not last. It is therefore of the greatest importance that we do not overlook any source of chronic poisoning when called upon to examine a patient with mental disturbance. A careful and thorough physical examination is more likely to be fruitful than investigation of the origin of the mental state along psycho-analytical lines.

### FOCAL SEPSIS OF DENTAL ORIGIN CAUSING MENTAL IMPAIRMENT

BY

W. R. ACKLAND, M.D.S., M.R.C.S.,  
CONSULTANT DENTAL SURGEON, BRISTOL LOCAL INFIRMARY

It has not been my fortune to treat any cases of definite insanity, but I have had a number of cases showing severe if non-certifiable mental impairment. I think my best contribution to the discussion will be to give you a short account of three of these.

*Case 1*—The brother of a professional man was brought to me during the war. He was a soldier on sick leave and for eight months there had been no improvement in his condition. He showed the most extreme degree of apathy. If sitting at table he would get up for something and forget before he had taken two steps for what he had risen. In speaking he would leave out words or break off in the middle of a sentence unable to finish. He was dull and listless, dispirited, slow, tremulous and uncertain in his movements. His complexion was a sickly earthy colour. He had some dull dental pain, which did not seem to be a matter of importance, but he had been persuaded to seek advice for this symptom. His mouth was in a terrible state full of crowns and bridges the roots supporting which were mostly suppurating. Under general anaesthesia a complete clearance of the offending teeth was made. Within a fortnight the good effect was apparent. His colour improved, his health became normal, his spirits returned and his mind became alert. He returned to his duty and has remained well since.

*Case 2*—A clergyman on a visit to Clifton was brought to me on account of offensive breath. His appearance was dreadful: his colour ashen grey, his speech slow, hesitating and indistinct. He showed an absolute lack of initiative and volition, and simply did what he was told in everything. He had had to give up his work owing to loss of memory. I found a mouth full of pyorrhoea with teeth mostly loose, and the odour beyond description. A complete dental clearance was made. His health, physical and mental, was restored to normal, he was able to go back to work, and has been busily employed ever since.

*Case 3*—A woman, aged 38, was white haired, wasted, and looked 50. So great was her mental torpor that she showed a long latent period between hearing a question and giving the answer, so that one was inclined to think her deaf. The answer when it came showed that her mental processes were sound. She was suffering from sleeplessness and neurasthenia and was extremely thin. Her mouth was in a shocking state, the few teeth she had left were either loose from pyorrhoea or dead and affected by periostitis. All the others had fallen out. Extractions produced a marvellous effect.

It is interesting to consider the route by which the toxin in these cases reaches the general circulation. In what for convenience I call the "open sepsis" of pyorrhoea the poison is swallowed, and perhaps, for a time, does little general harm. But presently the gastric defences break down, and absorption occurs. On the other hand, in the "closed sepsis" of apical abscess the absorption is directly into the circulation. In either case the toxin in the circulation probably directly affects the brain.

### DISEASE OF THE ANTERIOR ETHMOID CELLS AS A CAUSE OF OPTIC AND RETROBULBAR NEURITIS

BY

J. A. GIBB, M.D., M.Ch.,  
SURGEON TO THE EAR, NOSE & THROAT DEPARTMENT OF THE  
WEST COAST ORTHOPAEDIC HOSPITAL, GLASGOW

So far as I am aware there are no recorded cases of optic neuritis and retrobulbar neuritis due to disease of the anterior ethmoid cells.

During the last eighteen months four cases of optic neuritis and one of retrobulbar neuritis have been referred to me for examination by Mr. Potts, the surgeon to the ophthalmic department of this hospital, in each the evidence that the anterior ethmoid cells were diseased was definite. With the exception of the case of retrobulbar neuritis there was evidence that the maxillary antrum was involved, no doubt secondarily. Logan Turner and J. S. Fraser have drawn attention to the fact that a definite condition of the eye and a definite condition of the nasal sinuses or antrum should be present before operation, and that it should be clearly directed to the particular nasal condition. The surgeon should have a clear knowledge of the position and relationship of the various nasal sinuses. An x-ray photograph will show if any of the cells are abnormally placed. Transillumination of the frontal sinus and maxillary antrum is an important aid in diagnosis. The directional action of the everted epithelium lining the various cavities should be known.

It is now known that nasal sinus disease may be a cause of albuminuria, arthritis, and certain toxicæmias. These are distant infections, and are curable by operation on the affected sinus or sinuses, but the question arises whether the bones walls may become affected and infection thus spread to the overlying optic nerve. This may be possible in disease of the sphenoidal sinus and posterior ethmoid cells, but does not seem possible in the case of disease of the anterior cells. If infection does not spread by the blood stream nor by contact then I would suggest that spread takes place by the lymphatics. The lining membrane of the orbit and the sheath of the optic and third nerves are continuous, and the lymphatics must be continuous. Moreover, the nasal lymphatics can be injected through the lymphatics of the frontal region.

#### DIAGNOSIS

Cross infection of the sinuses with a large flow of pus, with swelling and moisture of the mucous membrane of the nares, does not seem to be a necessary condition attending optic nerve disease. The most severe cases are those in which the mucous membrane is dry and the pus thick and scanty. In them operation yields the most favourable and dramatic results. In anterior ethmoid disease pus is seen in the anterior part of the middle space, and in the posterior nasal space it is seen winding round the Luschka's cartilage. The position of the referred pain is a useful guide to anterior cell disease. It is assumed that cases of optic neuritis due to causes other than nasal sinus disease, such as cerebral pressure, cysts, etc., of the pituitary fossa, testicular syphilis, or nephritis, will not come into the hands of the rhinologist, but he should be able to say quite definitely whether or no his help will be of use. If the relationship of the rhinologist and the ophthalmologist had been closer in the past, as present-day knowledge impels it to be, then Mr. Rudyard Kipling would have wrought a happier ending in his book *The Light that Failed*.

#### OPERATION

I remove as little as possible of the middle turbinate bone. Anterior turbinectomy is all that is necessary. In a punch forceps and a small ring knife to open the cells. Complete excision may be necessary, and I have even felt the instrument to be in contact with the soft tissues of the orbit. Ecchymosis of the eyelids sometimes follows, it causes no inconvenience to the patient and is soon absorbed. I use lavage for some days previous to operation, if improvement takes place then no operation may

be necessary. An important matter in the after-care of these cases is warmth and free ventilation. If I quote the notes of two cases I think it may be sufficient.

## CASE I

I was sent for on July 1st to see Mrs. J., aged 82. She complained of pain in the left eyeball and along the superior maxilla and almost complete blindness of the left eye. There was ptosis of the lid and the eyeball could only be moved slightly outward and downward; the pupil was contracted. I referred her to Mr. Lott, who reported well marked optic neuritis, central scotoma, paralysis of the third nerve and slight proptosis; he suggested that I might find some nasal trouble. She gave a history of an influenza cold in her head some few weeks previously. Examination showed swelling of the middle turbinate with mucopurulent discharge in the middle anterior part of the space, and in the post nasal space over the Eustachian cartilage, the maxillary antrum was dull. I advised operation as a possible cure. She consented and three days later, under general anaesthesia, I completely everted the anterior cells up to the soft tissues of the orbit. There was ecchymosis of both eyelids. Six weeks later she had completely recovered her sight and movement of the eyeball and ptosis and proptosis had disappeared.

## CASE II

F. C., a gardener, aged 22, was admitted to the eye department of the hospital on October 11th, 1924. Receding optic neuritis of the left eye was diagnosed. He complained of severe supra-orbital headache and occasional occipital pain, that he felt giddy, was sleepy at times and of nausea. On examination I found slight mucopurulent discharge coming from under the anterior end of the middle turbinate bone. In the post nasal space pus was seen winding round the left Eustachian cartilage, there was a similar condition on the right side but less marked. The report as to vision was R.V. = 6/5 (part) L.V. = 6/36. There was slight hyperaemia of the left disc, physiological pit filled in, and lamina not visible.

On October 12th left vision = 6/60. The following day, under general anaesthesia, the anterior ethmoidal cells were opened, right and left gently curetted, both maxillary antra burred and pus evacuated from the left.

On October 16th left vision = 6/36 and on October 27th 6/18. On April 23rd of this year it was 6/12. There is no active optic neuritis now present and vision is practically normal. This case was shown at the laryngological meeting in May, 1925.

## ARTHRITIS DEFORMANS OBSERVATIONS ON ITS ETIOLOGY AND TREATMENT

(Preliminary Communication)

BY

L. S. ASHCROFT, L. CUNNINGHAM, T. P. McMURRAY,  
AND H. S. PEMBERTON

(David Lewis Northern Hospital, Liverpool)

Under the term "arthritis deformans" (Vuchow) we have included all forms of non-specific hypertrophic or idiopathic, active or inactive, arthritis which we have encountered in a routine investigation of upwards of fifty cases, seen in our wards and privately. This investigation has been conducted from several sides.

1. *Clinical*.—Daily observation has been made in the wards for as long, in some cases, as six months.

2. *Bacteriological*.—The joints have been opened (T. P. McM.) in a large proportion of cases, and from them an organism has been recovered (L. S. A.) which is identical in every case in its cultural and biochemical features. This organism does not correspond to any organism which has been previously described in association with this or any other disease, in so far as we have examined the literature. In only one case has it been recovered from the synovial fluid, in all the others it has been isolated from either the membrane or articular bone. No lesions have as yet been produced in animals, so far only the intravenous inoculation of rabbits has been attempted. Nothing constant has been isolated from foci of sepsis, faeces, urine, blood, or fasting stomach contents.

3. *Metabolic*.—Routine examinations have been made (L. C., H. S. P.) of gastric secretion, basal metabolism, acid-base ratio, renal and hepatic efficiency, and of glucose tolerance. The outstanding features, so far, appear to be the large proportion of cases showing achlorhydria or hypochlorhydria, the practically universal diminution of carbohydrate tolerance, and the relative absence of acidosis, renal or liver defects, or of changes in the basal metabolic rate.

4. *Therapeutic*.—Apart from correction of deformities (T. P. McM.) and removal of focal sepsis wherever practicable, the only routine treatment employed has consisted in the use of large amounts of 0.4 per cent hydrochloric acid and a carbohydrate-free diet extending over a period of months. Improvement—first by diminution of pain and then by increase of mobility—has been obtained in practically every case, even without the removal of focal sepsis.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL.

#### A CASE OF REVERSE PERISTALSIS

A congenitally weak-minded boy, aged 13, recently had an attack of diphtheria, which was treated with antitoxin in ordinary doses. About ten days after his admission to hospital, and after all acute symptoms had passed off, he became very constipated and lost his appetite, his tongue becoming furred and dry. Ordinary aperients failing to produce an action of the bowels, a simple enema was administered. This was retained for about three quarters of an hour, when it was returned unchanged, he vomited at the same time, and the motion noticed in the vomit several pieces of oval brown substance, rather less than the size of a small walnut. On examining these about an hour later I found them to be typical, formed faeces. The boy was then quite comfortable, he had had the bowels moved, though by the mouth, and his tongue had already cleared. He has since made a perfect recovery, and his bowels have become normal after the use of aperients.

The enema appears to have set up a reverse peristalsis which carried the faeces from the colon to the stomach in something less than three-quarters of an hour.

Colwyn Bay

ROBERT E. LORD, M.D., B.Sc. Lond.

#### PROLONGED CHEYNE-STOKES RESPIRATION FOLLOWED BY RECOVERY

The following case seems of sufficient interest to be placed on record.

A male infant 1 month old, was brought to the C.M.S. Hospital Pakhoi, South China, at 11 a.m. on May 9th, 1924. The child was cyanosed, the temperature was 99° F., the pulse was very feeble (160), and the respirations very irregular (50 to 60). As there was some history of cough it was for the moment thought to be a case of bronchopneumonia but auscultation of the chest showed nothing abnormal, and suspicion fell on the alimentary system. The mother, who lived on a junk, said that as she had been short of milk she had, the previous day, given the child a quantity of 'yeet'. This concoction very popular among the local Chinese is made of flour, cane sugar and boiling water. Castor oil was given at once and 3 minims doses of brandy, diluted at intervals.

At 2 p.m. the temperature had fallen to 98° F. and the respirations had become markedly irregular and finally, an hour later, assumed the Cheyne-Stokes type. The temperature rose to 100° F. At night the condition of the child was critical. The breathing cycle was of 7 to 9 respirations, the pulse was very feeble and difficult to count. An injection of digitalin gr. 1/1200 and strychnine gr. 1/1200 was given, and a rectal saline containing 20 minims each of brandy and aromatic spirits of ammonia administered. The latter was not retained it was repeated at midnight and again at 4 p.m. On these occasions it was partially retained.

At 8 a.m. the next day the Cheyne-Stokes breathing was very definite, temperature 100° F. and pulse still running. The child could not swallow water.

At 10 a.m. 2 ounces of saline with the addition of 1/2 minim liq. strychninae was injected subcutaneously. This was followed by a very definite reaction and at noon the temperature had risen to 103° F. The child was then able to swallow a little water. The injection was repeated at 4 and at 9 p.m. and though the cerebral control over the breathing was still inhibited the temperature remained at 103° F. during the day and the length of the Cheyne-Stokes cycle increased to 16.

By the following morning the child was able to take the breast which had been massaged and the milk flow improved. The temperature was now about 102° F. and the Cheyne-Stokes cycle about 30. The breathing gradually became normal and by 4 p.m. after forty-four hours of Cheyne-Stokes respiration had become quite regular. The temperature fell steadily, and five days after admission became normal.

Apart from flatulence which was controlled by small doses of salol the infant made an uneventful recovery, and on the tenth day after admission was discharged. It was then feeding and sleeping normally and the mother had a full supply of milk.

As there is no reason to suppose that the preparation given had not been well boiled and was therefore sterile, it would seem that the child was suffering from an auto-infection which was the cause of the medullary centre being depressed.

A. J. WATSON, M.B., B.S. Dunelm

Leikhoi, South China

### ACCESSORY MAMMILL

A CHINESE woman, aged 25, complained on the second day of her puerperium of two painful swellings situated in either axilla. She stated that she first observed them when 15 years of age, they were then the size of a hazelnut. She consulted a doctor, who diagnosed them as "tumours," presumably lipomata, and no treatment was suggested. As they pained her at regular intervals she went, two years later, to a hospital, where a similar diagnosis was made and their removal was offered, operation was refused.

I found over each of these swellings an accessory nipple, and was able to express a small quantity of milk from each. In the following days the production of milk in both normal mammae was superabundant, and they required support. The accessory mammae shared in this full lactation, were freely secreting, and painful. It was felt that belladonna plasters were contraindicated lest normal and accessory mammae might communicate, and the mother so lose her milk or atropine be administered indirectly to the baby. It was hoped that involution would occur as a result of no demand being made upon their function if they were independent, and this has now taken place to some extent, although milk can still be squeezed from either.

These accessory mammae are perfectly formed, hemispherical, each superficially  $\frac{3}{4}$  inches in diameter (the normal mammae are 7 inches). They are symmetrically situated upon the anterior border of each axilla. The nipple is centrally placed, three-eighths of an inch in diameter.

DOUGLAS D. S. STEWART, M.R.C.S., L.R.C.P.

Northampton

## Reports of Societies.

### AUTO-INFECTION IN NEUROLOGICAL LESIONS

A MEETING of the Edinburgh Medico-Chirurgical Society was held on June 3rd, with Sir DAVID WALLACE, President, in the chair.

Dr CHALMERS WATSON showed two cases of disseminated sclerosis to illustrate some of the points of his communication—The role of auto-infection or auto-infection in the etiology of disease of the higher and lower nervous systems.

The first case was a patient whose illness had lasted ten years, commencing with pruritus affecting the soles of the feet, gradually spreading up to the elbows and thighs, and later affecting the small of the back. This condition remained stationary for a year or two. Later she developed some insensitiveness and certain brain symptoms, but improved after a time in hospital. Now she had a recurrence of her symptoms showing Rombergism and a typical ataxic gait. Dr Watson wished to emphasize the importance of the general medical examination, to find out to what particular strain the patient had been subjected. In many cases the condition which this patient showed was found. She suffered from pronounced pyorrhea and constipation of the seven to eight day type. The urine, in accordance with Dr Watson's experience of most of these cases, was comparatively normal—free from albumin and sugar and practically free from bacteria. The other patient was an ex-serviceman who was perfectly healthy up to the time he contracted a severe dysentery. His signs showed a good deal of disturbance in co-ordination. He had a marked gastro-intestinal lesion, and a specially prepared vaccine produced distinct improvement.

Dr Watson drew no particular conclusions from these results except that they were interesting and stimulating, but his reason for showing the cases was to emphasize the association of these physical disorders with these neurological lesions. He referred to the view of French alienists of a hundred years ago, that mental disorders had their origin in abdominal disorders. This teaching had been largely disregarded, and though neurologists had added much to their knowledge of the symptoms and minute anatomy of disorder of the lower nervous system, corresponding advance in the knowledge of etiology and treatment had not been made.

Dr Watson referred to his views as published since 1900, on the factor of auto-infection taking origin in one or other of the mucous surfaces of the body—for example faulty state of teeth and gums, abnormal conditions of the digestive tract as revealed by physical examination, examination of the stools, and x-rays, and abnormalities in the urine, more especially the presence of bacteria and cells. He referred to the recent work on disseminated sclerosis, and to the conclusion tentatively drawn by experts from it, as to the intestinal tract being the primary source of the toxic agent responsible for the changes in the nervous system.

Dr ROBERT ROBERTSON agreed that in early cases of disseminated sclerosis something could be done for patient by studying their cases from a general point of view. Dr Chalmers Watson indicated. He recounted several cases in which removal of septic foci produced considerable amelioration in the nervous system symptoms.

### Tryparsamide in Syphilis of the Nervous System

Mr DAVID LEES then read a communication—a preliminary note—on the use of triparsamide in the treatment of syphilis of the nervous system. He referred to the composition of the drug and to the fact that it was not a powerful treponemacidal agent, its use in the treatment of syphilis being based on other considerations: (1) a powerful stimulative effect on animal economy and on animal resistance, (2) a high degree of penetrability, and (3) a fair or moderate degree of treponemacidal action which, on account of the unusual penetrability of the drug, was equally available for therapeutic purposes in all parts of the body. Mr Lees said that in the beginning of 1924, by the aid of the Medical Research Council, he was able to commence the treatment of five patients, and up to now eighteen patients had been treated by this drug. All the patients suffered from syphilitic infection of the central nervous system, and showed both positive serological reactions and positive findings in the cerebrobiology of the spinal fluid. With few exceptions all had been intensively treated with salvarsan, mercury and iodides, and other forms of treatment, but none of them had shown that amount of clinical or serological improvement in their spinal fluid which justified any hope for any permanency as a result of this treatment, prolonged in some cases for three or four years. The drug was given intravenously in doses ranging from 2 to 3 grams weekly, the former being the initial dose. Mercury or bismuth was also given. Triparsamide was definitely contraindicated in patients with optic atrophy or other disease of the optic tract or albuminuria. No grave constitutional effects were produced. The immunity to disturbance of the liver was noticeable. One patient had severe jaundice under arsenobenzol. So far he had had 90 grams triparsamide and had shown no evidence of liver trouble. As a result of the treatment the general condition of most of the patients was markedly improved. They developed a sense of well-being, their cerebriation improved, and their power of application to work increased. The most marked change was in the cerebrospinal fluid. The cell count decreased in all cases. The amount of globulin progressively decreased. The cerebrospinal fluid under the Wassermann test became completely negative in three cases within a comparatively short period, averaging three months. Lange's gold sol test showed a marked improvement in every case. Mr Lees said that so far as he had been able to evaluate the drug it seemed to be specially

valuable in meningo-vascular syphilis, in early tabes, and in early general paralysis. It did not seem to retard or control advanced paresis. It did not appear to influence the blood Wassermann reaction to any appreciable extent, and so it would appear that adjuvant treatment with salarsan and bismuth should be given. Mr Lees showed six cases to illustrate his paper.

### EDINBURGH OBSTETRICAL SOCIETY

At a meeting of the Edinburgh Obstetrical Society held on June 10th, the President, Professor B. P. WATSON, in the chair, three interesting papers were communicated to the Fellows.

Professor J. A. KILGORN (Dundee) described a case of abdominal pregnancy secondary to tubal gestation, operated on by him after full term. The case was of interest as there were no abnormal signs during pregnancy, and it was not until the patient was going to the maternity hospital thinking she was in labour that she collapsed and fainted, and was admitted to hospital in a serious condition. The condition was diagnosed and the abdomen opened forthwith. On opening the sac fetal gas escaped, followed by a gush of about two pints of chocolate-coloured fluid, and a dead, but not macerated, foetus weighing 5 lb. was delivered. The placenta was easily peeled off with little bleeding, showing that the foetus had been dead for some time, though it was in a good state of preservation. The sac could not be removed owing to adhesions, and it was plugged with a Mikulicz tampon, which was removed in forty-eight hours. The patient made an uneventful recovery. The probability was that the gestation had occurred in the right tube, and had gradually eroded the upper wall and had passed with membranes intact into the abdominal cavity. Spurious labour probably had occurred one month before operation, as foetal movements had ceased at that time and there was a history of slight pain and uterine hæmorrhage then, the sac had become infected later.

Dr DOUGLAS MILLER described his impressions of a visit to certain American and Canadian obstetrical and gynecological clinics. As most of the chief cities had been visited in Dr Miller's two months' stay across the water, his impressions were of great interest, especially when he came to discuss the various hospitals and their regimes and compared them with those in this country.

Dr GIFFORD KENNEDY described a case of unusually slow foetal heart beat (80 a minute), which continued during a long first stage of labour and during the second stage also, but on delivery the child was found to be absolutely healthy, and nothing abnormal could be elicited on auscultation of the heart after birth.

At the annual general meeting of the Chelsea Clinical Society held at St. George's Hospital, Dr GORDON LANE, the retiring president, opened a discussion on Facultative diagnosis. By this expression he meant the employment of the practitioner's powers of clinical diagnosis without resort to laboratory assistance. He thought that perhaps too much reliance was placed upon certain methods of diagnosis without using that power of observation that was inherent in everyone, to a greater or lesser degree. This was, perhaps, especially the case in the diagnosis of functional derangement of the ductless glands. Dr C. O. HAWTHORNE laid stress on exact clinical methods, but was strongly in favour of describing what was observed, and being very exact in the deductions which were to be made logically from those observations. Messrs FITZWILLIAMS, FORBES, A. R. THOMPSON, and Dr CREWDSOM THOMAS took part in the discussion which followed.

At a meeting of the London Dermatological Society held at St. John's Hospital, Leicester Square, on Wednesday, June 17th, the annual oration of the society was delivered by Professor Dubreuilh of Bordeaux on Chronic sunburn and epithelioma of the skin. The annual dinner was held at the Frodoeur Restaurant, Professor Dubreuilh being the guest of the society.

## Reviews.

### TUMOURS AND CANCERS

If a philosopher, a physician, and a biologist agreed to co-operate in writing about cancer they would, it might be expected, produce a book of an unusual pattern which, if the co-operation were close, might resemble Mr HASTINGS GILFORD'S *Tumours and Cancers*.<sup>1</sup> The closer the co-operation of the three hypothetical authors of the hypothetical book, the more striking would be the resemblance of their product to the volume Mr Gilford has produced, for in it we meet the philosopher, physician, and biologist in every page and every paragraph.

The title of the book gives no indication of its distinctive character, and even the qualification "A Biological Study" adds little to satisfy the curiosity awakened by a glance through the table of contents. Here we notice that the volume is divided into eight books, whose titles are—"Introduction, growth and overgrowth," "Development," "The origin of cancer," "Nature and natural history of cancer," "The cause of cancer," "Cause and prevention of cancer," "Retrospect and prospect." Those who take the plunge to find what it is all about will have to wade to a good depth before their curiosity is satisfied, and it may perhaps happen that, even after reading Books V and VI on the natural history and cause of cancer, they will not find it easy to say in a few sentences what they have learnt.

To understand Mr Gilford's views about cancer we must first appreciate the sense in which he uses the word "development" and its distinction from "growth." "Growth is a quantitative change with no reference to quality. To develop, on the other hand, is to become more intricate, to advance in complexity or quality. Though a thing may grow it does not necessarily develop, and though it may develop it need not grow" (p. 32). "Development either makes for progress or is regressive, with a tendency to work back in the form of a *reductio ad antiquum*. Regressive development is but another name for degeneration" (p. 77). He looks upon development, therefore, as first a progressive and later a regressive change, it is essentially a circular movement, "beginning with integration from inorganic elements and ending in disintegration into inorganic elements" (p. 627). Mr Gilford looks on cancers as variations of the regressive development of single cells or cell groups, whereby they become quasi-embryonic and proliferate. Elsewhere the biologist in him speaks of cancers as composed of cells which have been stopped in their upward development, and as a consequence unduly hastened in their downward development. When the physician enters, cancer is referred to as "Nature's punishment for a biological crime", and when the philosopher steps forward he refers to cancer as the "captain of the degenerations," a motley company which includes defective intelligence, imbecility, idiocy, insanity, diabetes, tabes dorsalis, dementia, epilepsy, neurasthenia, alcoholism, and others. All such degenerations are, the author holds, becoming more common as civilization advances.

Such are some of the distinctive ideas of the book. We do not quote these passages as standards by which the book should be judged, but mention them as indicating its general character, in the hope that what we have said may invite others to study it for themselves. It is stimulating matter to read, because on almost every page some provocative idea or some startling generalization is to be met. In particular, Book III deserves special recommendation, for this scholarly and philosophical essay on normal and premature development is a masterly exposition of a difficult chapter in biology. Having said so much in praise, we feel compelled to draw attention to one fault: the book is unconscionably long. It ought to be read through without too much interruption if the thread of the argument is not to be lost, but how many readers will have the leisure or perseverance to continue faithfully to page 700? If

<sup>1</sup> *Tumours and Cancers*. By Hastings Gilford F.R.C.S. With an introduction by Sir Frederick Keeble (B.L.S., Sc.D., F.R.S., London). Selwyn and Blount Ltd. 1925. (Roy. 8vo. pp. xii + 703. £2 2s. net.)

repetitions had been avoided all the information might have been given in perhaps half the space. If Mr Gilford finds that this imposing book does not reach so many busy people as he wishes, it is to be hoped that he will offer the medical world a more compact and less expensive statement of his views.

### PROBLEMS OF PERSONALITY

A STRINGS of studies by well known American, English, French, and Swiss psychologists has been published in a volume entitled *Problems of Personality* as a tribute to the pioneer work of Dr Morton Prince in the sphere of psychopathology. In his early years Dr Prince wrote a number of papers on general medicine and neurology, but he soon began to take a special interest in abnormal psychology. The *Dissociation of a Personality*, in which the complex disintegrations of an hysterical case are portrayed and interpreted, is probably his best known work, and it is interesting to note that he was writing on hypnotism, post-hypnotic suggestion, automatic writing, and double personality in 1890, at about the time when Pierre Janet published his famous work, *L'Automatisme Psychologique*, in which states of mental dissociation were made the subject of psychological investigation. Dr Prince has undoubtedly done much to arouse interest in a previously neglected sphere of medicine, and he has well deserved the respect paid to him which has now found tangible expression in the publication of this volume.

The studies included in the volume are written by workers in both abnormal and normal psychology, and the subjects chosen by the various contributors naturally cover a wide range. As might be expected, many divergent points of view are expressed, and some of the essays are polemical in tone. The book certainly reveals the extent to which psychology and psychopathology are lacking in that coherence and unity which is found in other branches of science, but its contents indicate that considerable advances have been made in the understanding of the human personality since the days when Dr Prince began his investigations. There is much in this work which the psychopathologist will find of interest.

### PATHOLOGY

DR LUDWIG ASCHOFF, professor of pathological anatomy at Freiburg University, has published a series of lectures which he delivered in the United States during 1924, in a book entitled *Lectures on Pathology*. He appears to have travelled from one medical school to another, delivering memorial lectures and addressing medical societies, fourteen of these lectures are gathered together in this volume. The first is on the reticulo-endothelial system of the body, a theme on which Professor Aschoff can speak with paternal authority, for it was he who, in 1913, first proposed this designation for the reticulum cells of the splenic pulp and lymphoid apparatus and the reticulo-endothelial cells of the lymph nodes, blood sinuses of the spleen, capillaries of the liver lobules, bone marrow, adrenal cortex, and hypophysis. He proposed this name because these cells have in common the function of producing reticulum and of lining sinusoid blood and lymph spaces, they act simultaneously as lining endothelial cells and producers of reticulum. That this conception of the reticulo-endothelial system was correct, and the introduction of a new phrase justified, has been supported by the results of many careful studies in microscopical anatomy, and the term "reticulo-endothelial system" is coming into general use. Professor Aschoff's lecture is concerned chiefly with the significance of the reticulo-endothelial system in blood destruction, blood production, and general metabolic functions. The first lecture makes its chief appeal to the histologist, the second, on the pathogenesis of human pulmonary tuberculosis, to the physician, and the fourth, on pathological fatty changes,

will be welcomed by the biochemist. In fact, Professor Aschoff has something to say to nearly everybody, as a bare mention of the titles of the remaining lectures will show. Of these the more important are those on the morphology of the suprarenals, arterio-sclerosis, ovulation and menstruation, the origin of gall stones, the site and formation of bile pigment, the goitre problem, and renal secretion and renal disease. Dr Aschoff in his preface acknowledges his indebtedness to "various gentlemen" who translated the lectures and assisted in their preparation for publication, and he has been fortunate in their help, for the book reads easily without reminding us that it has been translated from another tongue.

*Pathological Technique* by Dr F. B. Mallory and Dr J. H. Wright, has long been a popular book with laboratory workers, and has now reached an eighth edition. It was first issued in 1897 as a practical manual for workers in pathological histology and bacteriology, has grown with the times, and has been built up into a rather expensive but almost indispensable book of reference. For the information of those who do not know the book we may say that it covers the whole field of practical pathology, having sections on histological methods, culture media, microscopical examination of bacteria and fungi, animal parasites, serological technique, and post mortem examinations. The main differences those familiar with previous editions will notice are that the chapter on blood has been rewritten and now presents both the technique of examination and the clinical interpretation of results, that the divisions devoted to bacteriology and serum diagnosis have been enlarged, and that brief directions have been added for photomicrography and the photography of gross pathological specimens. The book has grown to more than 660 pages, with 163 illustrations.

### OPERATIVE SURGERY

THE fourth volume of Dr W. S. Bickham's treatise on *Operative Surgery* deals with thoracic and abdominal surgery and maintains the even and high standard of its predecessors. The descriptions of the operations, which are on the same plan as in the previous volumes, are detailed and alternative methods are given. On the whole the work is written on conservative lines—that is, methods which have been tried and tested are explained, and although it is well up to date the text has not been allowed to digress into controversial matters. On the big subject of gastric surgery the author quotes mainly the work and methods of the Mayos, Moynihan, Billroth, Balfour, and Kocher, and for statistics draws largely on the work of the Mayo Clinic. How recent the statistics with reference to Rammstedt's operation for congenital hypertrophic stenosis are it would be interesting to know, as the average mortality quoted is about 18 per cent. Perhaps the most disappointing chapter, especially in a book of this kind, which must be mainly one of reference, is that on the surgery of the spleen. Here we find little allusion to the "medical" spleens and their relation to splenectomy. The chapters on the biliary apparatus and intestinal surgery are good in that the illustrations are chosen with special reference to the display of operative technique. In the earlier chapters Trendelenburg's operation for embolism of the pulmonary arteries is described, and also three alternative methods of massage of the heart with their relative values are given.

The first section of the fifth volume is concerned with what is called the colo-recto-anal tract, in it are described the various modifications of the operations for colostomy, excision of the colon and rectum, colopexies and colopexions, haemorrhoids, fistulae, and the congenital abnormalities of these parts. It is surprising to find that, in

*Problems of Personality*. Studies presented to Dr Morton Prince. Pioneer in American Psychopathology. Edited by C. MacFie Campbell, H. S. Langfield, William McDougall, A. A. Roback, and E. W. Taylor. The International Library of Psychology, Philosophy, and Scientific Method. London: Kegan Paul, Trenchard, Trubner and Co. Ltd. New York: Harcourt, Brace and Co. Inc. 1925. (Demy 8vo pp. xiii + 434 18s net.)

*Lectures on Pathology*. By Ludwig Aschoff. M.D. New York: Paul B. Hoeber Inc. 1924. (Med 8vo pp. x + 363 35 shillings 5 dollars.)

*Pathological Technique*. By F. B. Mallory, A.M. M.D. and J. H. Wright, A.M. M.D. S.D. Eighth edition revised and enlarged. Philadelphia and London: W. B. Saunders Company. 1924. (Demy 8vo pp. 666 163 figures 32s 6d net.)

*Operative Surgery*. By W. S. Bickham, M.D. F.A.C.S. Vol. IV and V and index volume. Philadelphia and London: W. B. Saunders Company. 1924 and 1925. (Roy. 8vo Vol. IV pp. iii + 842 77s figures Vol. V pp. iii + 880 111s figures Vol. V pp. iii + 620 122s figures 50s net a volume £15 the set index volume free. Sold in complete sets only.)

dealing with the question of haemorrhoids, injection with carbolic acid is not mentioned. The major part of the volume is devoted to the genito-urinary tract, it contains a vast amount of information, and the author has not spared himself when dealing with such subjects as plastic operations on the ureters, operations for epispadias and hypospadias, and ectopic vesicle. The modifications described are legion. Textbooks are apt to slur over such subjects as the manner of using cystoscopes, urethrotomes, lithotrites, and evacuators, but here a very satisfactory account is given. In spite of the facilities afforded by ureteric catheterization, Lums's separator still maintains its hold on the textbook. Dr Bickham seems to have a partiality for Kelly's direct method of cystoscopy and ureteric catheterization in the female. It is difficult to understand why separate methods should obtain for the two sexes. If it is necessary to master the details of the cystoscope for the male, it would seem far simpler to apply them to the female as well.

The sixth volume, with a separate volume for the general index to all the volumes filling some 190 pages, brings to a close this vast compilation on surgical operative procedure. The sixth volume, after dealing with operations upon the ejaculatory ducts and prostate, proceeds to describe obstetrical and gynaecological operations. The final chapter is devoted to deformities and disabilities of an orthopaedic nature not included in the earlier volumes. The operations on the prostate are very fully discussed, and the liter methods, such as partial prostatectomy by the intraurethral punch method, and transurethral prostatectomy by various criteria for prostatic obstruction, are described. The gynaecological operations are fully detailed and illustrated, and special attention has been given to the numerous plastic devices which are employed in these regions. Where special instruments are required these are clearly illustrated. The midwifery section deals with delivery, version, Caesarean section, and the surgical treatment of the complications associated with pregnancy.

It must be with a great sense of relief that the author can survey the completion of his task. It has been an immense undertaking, and is thoroughly well done, but the volumes, it appears, are not sold separately, and how many surgeons will care to spend so large a sum as the publishers demand for a single book remains to be seen.

### VOLUMETRIC ANALYSIS

SUTTON'S Volumetric Analysis has been a standard work for many years. The fact that it has passed through ten editions is substantial testimony of the appreciation in which it is held. The reason, we think, is not far to seek. It is a manual of technical chemistry as well as of volumetric methods. There are few chemical operations of a quantitative nature in which some attempt has not been made to subordinate them to a volumetric process, and few that cannot be made by one plan or another to yield trustworthy results in the hands of a practised operator. Some of these, it must be confessed, involve such cumbersome preparation that they are only useful when needed repeatedly, a single demand is more expeditiously discharged by a non-volumetric method. In many cases, however, there is no choice but to resort to some form of volumetric process. It is for these cases that the value of the work is inestimable. The new edition<sup>6</sup> describes methods for the determination of a number of materials not treated of formerly and gives a large choice of methods for dealing with operations provided for in former editions. Published methods of procedure have been multiplied so extensively in recent years that there is a danger of some of the best being overlooked among the multitude and thus omitted from the mere lack of space to include all of them. Instances of such omission were inevitable, but the book has the saving merit of containing within a remarkably manageable space a most comprehensive collection of the directions and data needed for laboratory operations. From our first view of the

variety of subjects treated we expected to find a chapter devoted to methods for the chemical determinations employed in physiological laboratories, but none is the only physiological subject we found in the index. The text of the volume appears commendably free from error, and the quality of its contents will maintain the status which the work has so long held.

### THROAT BIOPSIES

The term "biopsy" was introduced into dermatology by Darier to describe the excision and histological examination of a fragment of tissue from a lesion in a living patient in order to elucidate or confirm a diagnosis. Dr AMY has, in *La Biopsie Clinique en Oto-Rhino-Laryngologie*,<sup>7</sup> elaborated in a substantial volume the application of this principle to oto-rhino-laryngology. The information gained by this means does not necessarily stop at the confirmation or correction of a diagnosis, because the more exact and detailed this is rendered by the aid of histological examination, the more accurate will be the prognosis and the more precise will be the indications for treatment, moreover, in certain cases the progress of the patient and the results of treatment can be checked by repeated biopsies. It is almost inevitable that in such a book the author should appear to claim too much for a particular method, but he quite frankly tells of its limitations, its failures, and of the harm that may follow if it be employed in unsuitable cases.

The exposition of the subject includes the histological as well as the clinical and manipulative aspect, and there are numerous excellent illustrations of the histopathology of the special regions concerned.

The book is overweighted with long case histories, and the author would do well on a future occasion to cut these down ruthlessly and devote even more space to illustrations and histological detail. The book as it is does infinite credit to the industry of the author and to the teaching in the clinic of Dr Lemaître.

### BOOKS FOR NURSES

We cannot always find space to review textbooks written for nurses, but we have received two which we think deserve to be brought to the notice of our readers because they are books which give in a plain and trustworthy fashion the sort of information which is necessary for a nurse's education in her work. The first of these, *Elementary Anatomy and Physiology for Nurses*, by Dr H. CLIFFORD BARCLAY, is a book which has already proved its usefulness, for it has run to a third edition.<sup>8</sup> This well illustrated book explains the structure and function of the body in everyday language, and its teaching is made more easily assimilable because of the homely analogies with which the author explains his facts. Anatomy and physiology can only be rightly understood as sections of the larger subject of biology, a fact of which Dr Barclay frequently reminds the reader. "How can these dry bones live?" is a question which many a medical man preparing to lecture to nurses must have asked himself. A spark of physiology may light the fire, but plenty of biology is needed to feed the flames. Dr Barclay's book is well illustrated, and if the easy conversational style gives it a living interest to nurses we think that this success must be ascribed in chief to his wide biological outlook.

The other book, of larger scope, is the well established *Text-Book for Nurses* by Mr HENRY GROVES and the late Dr J. M. FORTESCUE-BRICKDALE. Since first published in 1912 this textbook has been in great demand, and fresh editions or impressions have been called for no less than ten times. The chief aim of the book, which deals with anatomy, physiology, surgery, and medicine, is to enable the nurse to understand the principles underlying the medical and surgical treatment which it is her duty to assist in carrying

Aub. n. Preface de M. le Prof. Agrégé T. Lemaître. Paris. Vigot Frères (Roy. Bro. pp. vii + 334. 39 figures. Fr. 30).

<sup>8</sup> *Elementary Anatomy and Physiology for Nurses*. By H. Clifford Barclay. M.D. Ch.B. M.R.C.S. L.R.C.I. F.R.C.S. Edin. Third edition. London. Baillière Tindall and Cox. 1924. (Demy Bro. pp. x + 411. 49 figures. 12s. net.)

<sup>6</sup> *A Systematic Handbook of Volumetric Analysis*. By Francis Sutton. F.I.C. F.C.S. Eleventh edition, revised throughout with numerous additions. By W. Lincoln Sutton, F.I.C. and Alfred E. Johnson, B.Sc. London. L.C.C. A.R.C.S.E.I. London. J. and A. Churchill. 1924. (Demy Bro. pp. vii + 629. 120 figures. 35s. net.)

wisely omitted. The medical section of the present third edition\* has been revised by Dr J. A. NIXON and to this section a chapter on hygiene has now been added. We need say no more of the scope of the book than that it covers the syllabus prescribed by the General Nursing Council and provides a good basis for studying for the examinations by which a nurse's knowledge is tested.

While speaking of books for nurses we may mention a useful little pamphlet by Miss Louise KINGHAM, matron of the Weymouth and Dorset County Royal Eye Infirmary, entitled *The Nursing of Eye Cases*†. It will give a nurse a clear appreciation of the relative gravity of accidents to the eye, and enable her to follow intelligently the various ophthalmic operations at which she may have to assist.

### NOTES ON BOOKS

THE volume on the human ciliary diaphragm‡ is the second of a series of ophthalmological monographs written by Professor L. BRIEN of Paris. The first, dealing with the cornea and sclera, appeared about a year ago, the third, on the lens, is announced as in course of preparation. In the volume before us the author includes the whole of the uveal tract anterior to the ora serrata. After a summary of the anatomy and physiology of the structures concerned, the nervous and muscular anomalies of the pupil and ciliary body are dealt with in a very clear and comprehensive survey. This section is the most useful in the book. The remaining chapters deal with the diseases of the region seriatim—inflammations, wounds, neoplasms, congenital abnormalities, sympathetic ophthalmia and glaucoma are also considered as being diseases peculiarly associated with the part in question. The monograph is clearly and concisely written, it is authoritative rather than discursive, it does not enter largely into detail, and never becomes overburdened. The illustrations are numerous, but some of them lack clarity.

The relations of dermatology to general medicine are illustrated in two short essays—on the relations of eczema to internal diseases§ by Professor S. EHLMANN, and on the relation of the genital organs to changes in the skin|| by Dr K. WIENER—both forming part of the series of monographs edited by Professor Jadassohn of Breslau and Professor Pinkus of Berlin. After definition of the term "eczematous diseases" Professor Ehlmann discusses the occurrence of eczema in various metabolic diseases, such as diabetes, the urea acid diathesis and nephritis, and then considers the subject of eczema of the outflow of the alimentary canal and genito-urinary tract. The final chapter is devoted to the description, diagnosis, and treatment of the condition variously known as eczema nummular, neurodermatitis circumscripta, and lichen circumscriptus chronicus (Vidal). Dr Wiener's study deals with the various dermatoses associated with puberty, menstruation, pregnancy, labour, and the puerperium, as well as those attributed to diminution, absence, or pathological increase of the activities of the sex glands. A bibliography of recent literature is appended.

The *Synopsis of Medical Terminology*,¶ by Dr M. J. SEIFERT, is a short dictionary of medical terms. It will be useful to students seeking the meaning of technical terms, and, we hope, a guide to anyone who may be labouring under a desire to coin a new word. To previous generations, well grounded in the classics, this book would have been valued only by the forgetful but to-day, when many students commence their course with less knowledge of Latin and perhaps none of Greek, it is likely that such a dictionary will meet a larger need. The habit of analysing all scientific terms greatly simplifies the study of any subject but since most medical terms have their origin in the Greek and Latin languages this good habit often requires the aid of a dictionary.

\* *Text Book for Nurses* by E. W. Hov. Cleave, M.D. B.Sc. M.S. F.R.C.S. and the late J. M. Fortepene Brickle, M.A. M.D. Oxon. F.R.C.P. Lond. The Medical Section revised by J. A. Nixon C.M.G. ¶ *Synopsis of Medical Terminology* by M. J. Seifert A.B. M.D. F.A.C.S. New York and London: D. Appleton and Co. 1925. (Demy 8vo pp. 30 3s 6d net.)

for its punctual observance. This book, after some observations on the general principles of medical terminology, gives an alphabetical list of medical suffixes, followed by a similar list of word root and an alphabetical list of prefixes. It occupies only thirty pages and it would perhaps have been more convenient if the book had been bound in such a way that it could be slipped into a pocket instead of being destined for the shelf.

Under the somewhat sonorous title of *Hygienic Fundamentals of Food Handling* an unpretentious little book has been prepared by two American writers, CHARLES THOM and ALBERT C. HUNTER. It contains much miscellaneous information often omitted from books on hygiene—about such subjects as the decomposition of eggs, the preservation of fermentable food, and the canning of fruit. On the other hand, it does not give a very good account of the common type of food poisoning due to the salmonella toxin. In this, as in other American books, *B. botulinus* occupies a much more conspicuous place among the agents which threaten danger to food than it does in English presentations of the subject of food poisoning. We cannot picture any one class of people to whom this book would be particularly useful, but we think that some bacteriologists and medical officers of health, whose duties bring them into touch with problems of the preservation of food, would find it useful for occasional reference.

### PREPARATIONS AND APPLIANCES

#### Kharulphan

THE Kharulphan brand of novarsenobenzol is a preparation made by Messrs Burroughs Wellcome and Co. Snow Hill Buildings, I.C.1, for subcutaneous and intramuscular injection. Its special feature is its great solubility; it dissolves rapidly and completely in its own weight of water or saline. As regards its lack of irritant properties the manufacturers state that it can be injected subcutaneously with a minimum of discomfort to the patient. The activity of the drug has been tested biologically under the arrangements approved by the Board of Trade and the Ministry of Health. This preparation should be found of great value by medical practitioners, for novarsenobenzol can be administered in this form with a minimum of trouble both to the practitioner and to the patient.

#### Hexamine and Methylene Blue

Messrs Burroughs Wellcome and Co. put up in tablets a combination of 3 grains of hexamine with 1/4 grain of methylene blue. The purpose of this combination is to enhance the well known action of hexamine as a urinary disinfectant. Methylene blue has a well marked action as a urinary antiseptic and acts equally well in acid or alkaline urine, whereas hexamine only acts under the former condition.

#### "Vacacneum"

"Vacacneum" is a vaccine prepared from *Staphylococcus pyogenes* and *Bacillus prodigiosus*. It is recommended for non specific vaccine therapy. A complete treatment it is stated consists of eighteen injections at intervals of two days. The makers claim that this treatment produces beneficial results in a number of conditions particularly in tabes and asthma. The preparation can be obtained from Messrs H. R. Napp Ltd., 3, Clements Inn, London, W.C.2.

#### "Otalgan"

"Otalgan" is a 5 per cent solution of phenazono (phenyl dimethyl pyrazolon) in anhydrous glycerin. The preparation is recommended for instillation into the ear for the relief of otitis media. This preparation also can be obtained from Messrs H. R. Napp.

#### An Ultraviolet Lamp

A new lamp for ultra violet radiation or 'artificial sunlight' (to use a term which is becoming discredited) has been introduced by the Medical Supply Association Ltd. (167 185 Gray's Inn Road, London W.C.1). Its distinguishing feature is that the radiation is obtained from an arc burning one pencil of tungsten and the other of carbon though if a more rapid reaction is desired both elements may be of tungsten. The visible illumination with this lamp is of less intense quality than with mercury vapour but there is no doubt as to the effectiveness of the ultra violet radiation. The lamp in the design of which the firm had the assistance of Dr Percy Hall is well constructed. The arc is contained in a polished aluminium hood which is supported on a vertical stand and this is mounted on a non base with rubber tyred castors. It has been stated that the carbon arc is the more useful for general treatment while the tungsten arc has its advantages in local use, as in the treatment of sinuses and discharging gland. This apparatus provides for both general and local irradiations the latter by means of a localizing mask which fits in front of the hood and carries a quartz lens. An extremely easy mechanism provides for horizontal and vertical movements and for a rotary movement around the support, the procedure of striking the arc and adjusting the elements is scarcely less simple than that of operating an ordinary electrical switch. The lamp has, we are informed, been manufactured entirely at the firm's London works.

## ROCKEFELLER MEDICAL FELLOWSHIPS.

## GREAT BRITAIN

The Medical Research Council announces that it has awarded Rockefeller Medical Fellowships, tenable in the United States of America during the academic year 1925-26, to the following

DAVID CAMPBELL, B.Sc., M.D. Glas., Pollok Lecturer in Pharmacology and Therapeutics, University of Glasgow

WILLIAM NORMAN CRAIB, M.C., B.A. Camb., of Good Hope, B. Chir. Camb., House Physician, Guy's Hospital, London

MISS KATHERINE HOPE COWAN, M.Sc. Manch., D.Sc. Lond., Assistant in Biochemistry, University College, London

WILLIAM SIFONRIED DAWSON, M.A. B.M.Oxf., M.R.C.P., Senior Assistant, Maudsley Hospital, London

HOWARD WILLIAM FLOREY, M.B. Melb., B.A. Oxf., John Lucas Walker Student, University of Cambridge

ARTHUR DAVIN RITCHIE, M.A. St. And., B.A. Camb., Lecturer in Physiological Chemistry, University of Manchester

GEORGE PALLING WRIGHT, B.A., B.M.Oxf., Macgregor Student and Demonstrator in Histology, University College, London

Dr Craib, Dr Florey, and Mr Ritchie have been appointed on modified conditions, while holding scholarships or emoluments from other sources. Mr Ritchie's Fellowship is being held during a short period of work in Canada this summer.

## EPSOM COLLEGE

The annual general meeting of the Governors of Epsom College was held on June 26th, with the chairman of council, Dr Raymond Crawford, in the chair.

The chairman said that he hoped this would be a memorable year in the annals of the college and one pregnant of far-reaching results. Increased support from the profession and others had enabled the council to face increased commitments in various directions. In its determination to attain the highest educational level, it had made substantial improvements in the pecuniary prospects of the masters. The year had seen the completion of the rebuilding of the chapel as a memorial to the masters and boys who fell in the war. The new chemical block, thought and talked about for so many years, was now actually in hand, and had been made possible by several generous bequests. The vacated space would afford much needed additional accommodation for classrooms and lecture-room, and for a natural history museum, much better than that they now had. The council was now in a position, by the munificence of a benefactress, to carry out a complete transformation of the existing library, and to make it far more attractive and serviceable to the boys than in the past. The chairman expressed the hope that similar help from some other quarter might be forthcoming towards the equipment of a museum worthy of a school that supplied so many recruits to scientific professions. £500 would solve all difficulties in that direction. Another need of the college was the leveling and extension of some parts of the playing fields, so that all the boys might play their games under more inspiring conditions. The bursar had secured an estimate for the work, which showed that it could be well done for £1,500. These things were beyond the capacity of the normal revenue of the college, which this year was bearing the cost of an extensive substitution of electric light for gas, and which would almost at once have to provide better washing and drying facilities in the Lower School and probably in the not distant future to undertake the centralization of a scattered and wasteful system of heating and hot water supply.

The chairman concluded on a note of gratitude to all who had helped them to their good subscribers, donors, and benefactors, to their organization of local secretaries, which he wished to extend far more widely, to the great medical institutions, the British Medical Association and *British Medical Journal*, the *Tanet*, the Medical Insurance Agency, and numerous Panel Committees, to Mr Gerald Stanley, who had established at his own expense a scholarship giving free education at the college, and to Mr Arthur Chudleigh, who had given to the chapel a silver-plated cross, six candlesticks and vases for the altar, and in which dish

He hoped that the generosity of all these might prove contagious in many quarters.

On the motion of Dr de Havilland Hall, seconded by Sir St Clair Thomson Dr Raymond Crawford was appointed a vice president of the college in recognition of the fact that he had collected over £1,000 for the Royal Medical Foundation attached to the college.

## Pensions and Scholarships

The scrutineers, Dr E. Climson Greenwood, Dr Raymond Crawford, and Sir William Hale-White, reported the successful candidates to be as under

Pensionerships	Votes
* Baynes, Donald	4,755
† Ayres, Edith C.	2,004
† Chatterton Percy	1,468
† Stephenson Hilda	1,440
† Goulston Arthur	1,428
† Willis, Joseph D.	1,399
† Kennedy, Florence A.	1,354
† Shaw, Annie C.	1,124
* Christie pensioner	† Ordinary pensioners
† Pugh pensioners	

## Foundation Scholarships

	Votes
McClintock, John H. T.	10,764

Allen, Edward V. M.	8,863
Pinniger, John L.	8,208
Burgess, Christopher J. V.	6,648
Ryle, Ian N.	6,319
Marsh, Thomas A.	6,201
Sanderson, Paul B.	6,026
Wolfenden, Henry C. L.	5,665
Farman, Henry C.	5,095
Kee, Eric M.	4,821

## MENTAL INVALIDS

THE Moulton Lectures for 1925 were delivered in the Royal College of Physicians, Edinburgh, by Dr C. C. Easterbrook, Physician Superintendent of the Crichton Royal Institution, Dumfries, on June 22nd, 24th, and 26th. He took as his subject "Mental invalids."

## The Body-Mind

In the first lecture, on the "Body-Mind," he dealt with the conception of the biopsychic nature of the human organism in health, in bodily disease, and in mental disease. He maintained that the integration of the various parts of the organism into a working unit had been effected by the nervous system at gradually ascending levels of its activity corresponding to the phylogeny of man's adjustment with environment, and was represented from below upwards by the vegetative, sensorimotor, and mental provinces of the nervous system. The first of these in its sympathetic and autonomic parts integrated the biological machinery of metabolism, growth, development, and decay, and differences had to be recognized between sympathetic-tonic and autonomic individuals. The sensorimotor nervous system integrated the motor machinery of the body and its parts, and recent work on the constitution and innervation of the skeletal muscles showed that this part of the system had a bearing on the peripheral explanation of the genesis of emotion. The mental nervous system integrated the mental machinery of the body and its parts, subvocal conscious and unconscious mental activity, and its highest level in the cerebral cortex, unified and expressed the individual, put him in relation with his environment, and regulated his conduct. Consciousness—that is self-consciousness—was to be explained by stimulation of the cerebral cortex from within or from without the body. With regard to unconscious mental activity, man's origin of mind must be regarded as coextensive with his body. The new psychology stressed the importance of feeling, desire, and instincts in human mentation and conduct, and lowered the influence of reason, moral sense, will, and self-control, the higher qualities of mind which distinguished man from animals and had made him the master. The lecturer observed that the terms of physics and chemistry were inadequate in biology, and still more so in psychology, for the terms of each science had their own distinctive meaning, and in man biological and psychological occurrences were unique.

\* See BRITISH MEDICAL JOURNAL, February 28th 1925 p. 422.

### *Clinical Examination, Causation and Prevention of Mental Diseases*

In the second lecture Dr Easterbrook dealt first with the clinical examination of mental invalids, and detailed what he considered to be in ideal form of clinical record. He then went on to consider the causation of mental diseases and their prevention. He expressed the opinion that it was better to regard the two great factors productive of mental disease as a nervous constitution, inherited or acquired, which was a predisposing factor, and stress, which was an exciting factor, rather than, as was commonly done, to speak of heredity and stress. The nervous constitution, inherited or acquired, was the essential causal basis of a mental breakdown, and it was very important that it should be recognized by the individual. The sources of evidence of this constitution were six in number—namely: (1) The presence of some congenital nervous, mental, or moral defect. (2) The occurrence in previous life from infancy onwards of some acquired psychosis, psychoneurosis, or neurosis. (3) The occurrence in earlier life of periodic or persistent morbid tendencies—that is, faulty habits and vices. (4) The presence of an abnormal temperament, either inherited or acquired, which was the most frequent and the most subtle sign of a nervous constitution and specially important to recognize, this might include the unusual development of such qualities as irritability, jealousy, waywardness, optimism or pessimism, etc., or it might take the form of an abnormal conflict between the instincts of the "herd" and of self-preservation. (5) The presence of a nervous or degenerate physiognomy and physique had to be considered, but, in the lecturer's opinion, this was apt to be artificial, and was not of great importance. (6) A family history including the occurrence of mental and nervous diseases and of morbid disposition and habits among the individual's nearest blood relatives. Dr Easterbrook classified the various stresses or exciting factors which might produce mental disease in seven classes, which included direct pathologic stresses involving diseases of the nervous system, indirect pathologic stresses involving bodily disease, metabolic disorders, and endocrine disorders, toxic stresses such as the action of alcohol, cocaine, lead, etc., on the nervous system, energetic stresses, which included external agencies producing shock, exhaustion, and poisoning of the nervous system, hygienic stresses, including privations or excesses in mode of life, biologic stresses, including abnormal changes occurring in the organism during the mental and reproductive epochs and crises of life, and psychic stresses, including excessive mental perturbations, such as prolonged worry, and privations, such as solitude and want of occupation.

### *Classification of Mental Diseases, Curative Treatment*

In the third lecture Dr Easterbrook dealt with the classification of mental diseases, and added some remarks on methods and aspects of curative treatment. He proposed a nosological classification of mental diseases by which they were divided into the congenital psychoses, such as mental defectiveness in its various grades, and the constitutional psychoses, which included melancholia, confusion, dementia, delusional insanity, and the psychoneuroses, etc. He pointed out that the great autonomic feature of these disorders was chromatolysis of the cortical cells, which became unduly worn out, and of which numbers disappeared, the organic psychoses included conditions such as cerebral sclerosis, haemorrhage, tumour, and other gross nervous lesions, the organismal or "bodily" psychoses included a great number of infective and other bodily diseases which produced an indirect mental effect, the toxic and energetic psychoses included the influence of drugs and the various energetic traumatism. The lecturer next considered some aspects of curative treatment. He pointed out in the first place the great importance of the movement which was at present taking place for the voluntary admission of patients to asylums. In 1900 the number of voluntary private patients admitted into the Royal and District Asylums in Scotland had been 84 while in 1924 the number had risen

to 431. This was of special importance in regard to the early treatment of mental disease. He considered that no general hospital or medical school could be regarded as complete without its psychiatric clinic. He attached great importance to the open air rest treatment in active psychosis, and showed plans of buildings specially adapted for this purpose. In regard to endocrine therapy, it had, he said, been found that most glandular extracts in all probability acted simply because of their large nucleoprotein content, and without reference to the particular gland from which they were derived. Thus, however, did not apply to thyroid extract which in large doses continued for a week, produced a marked catabolic effect with loss of weight, when the thyroid administration was stopped at the end of a week, a marked anabolic rebound took place in which the patient not only gained quickly in weight, but in which the mental symptoms were likely to disappear, thus greatly shortening the period of treatment.

### THE HEALTH GOVERNMENT OF GERMANY

The League of Nations, in continuance of its policy of giving information to its constituent members in matters of international importance, has issued two statements on the subject of public health services, one relating to Germany, the other to Austria. They have been prepared, the former by Dr. Gottfried Levy, medical director of the central health office in Berlin, and the other by Dr. Hermann Schloetter. The pamphlets, which contain 60 and 80 large octavo pages respectively, would have been much the better for tables of contents. The subjects dealt with include notification of infectious diseases, the procedure for their investigation, the periodic publication of statistics, the registration of births and deaths, public health legislation and sanitary organization, sanitary equipment, hospitals, sanatoriums, lunatic asylums, etc. the campaigns against tuberculosis and venereal diseases, the protection of maternity and of babies and children, housing, water supply, and drainage, and, finally, the control of foodstuffs. Germany is a federation of eighteen States which possess the right of enacting their own laws, so long as the central authority (Reich) does not use its legislative power.

### *Notification of Disease and Registration of Death*

The reader will find many differences between German and English administration. Notifications of infectious disease are made to the police authorities, and by them are forwarded to the district medical officer, any change of the place of residence of an infected person must be intimated to the police of both areas. In puerperal fever the medical officer may only visit with consent of the householder, which, however, is seldom refused. Where anthrax, glanders, dysentery, or typhoid fever occurs the police may order an official post-mortem examination, "if possible by a doctor," before burial. The Reich has not yet adopted the international system of registering causes of death. The birth of a stillborn child must be notified on the following day to the registrar. Illegitimate births must be notified within a week by attending midwives. A stillbirth is defined as one in which no pulsations of the heart are observable after issue from the womb. As regards deaths in general, "the accuracy of entries in the annual 'causes of death' is in the main ensured by the fact that these statistics extend to all the towns, in which medical post-mortem examination is generally compulsory." Registration, however, is done by non-medical persons, and apparently a medical certificate is unnecessary, in some places post-mortem examinations may be made by barber surgeons or "layers-out." Statistics are given for various States showing that in 25 to 30 per cent of fatal illnesses there was no medical attendance.

### *Health Officers*

Candidates for appointments as State health officials must follow a specified course of study and examination. The subjects include forensic medicine, psychiatry, social hygiene, pathological anatomy, and bacteriology. If a

candidato fails to pass any part of the examination he is not allowed to come up for re-examination more than once. "In Prussia it is a condition of appointment as Kreis (district) medical officer that the candidato should have worked five years as an independent medical practitioner after passing the examination." The word "after" will be noted in this quotation as indicating a conception and scheme quite different from that of this country. The same officer deals with public health and forensic medicine, and must have had considerable experience in general practice.

The English reader will find in the pamphlet a curious reminder of the old practice of affixing warning notices to houses in which there are cases of infectious disease. "The marking shall be in a conspicuous place and shall be in the form of a yellow signboard by day and a yellow lantern by night." These marks are required for typhoid fever and relapsing fever. The campaign against alcoholism occupies an important place in Germany.

In Germany the State authorities have always given the fullest attention to the social consequences of alcoholism—for example, the deterioration or destruction of efficiency, increased debility of health and mortality, undermining of family life, degeneracy in children and increased crime and vagrancy. The following measures have been taken by the Government: the establishment of a Reich monopoly for the production and sale of spirits entailing higher prices and consequently lower consumption; restriction of retail sale on dry days in certain highly industrialized districts; prohibition of the hawking of spirits, encouragement of the establishment of temperance hotels and of the production of non-alcoholic refreshing and stimulating drinks; licensing regulations, control of imports, general popular education, and lastly, legislative measures for placing drunkards under guardians or trustees and confining them in sanatoriums.

A considerable percentage of the surplus proceeds of the brandy monopoly (amounting to 20,000,000 marks in 1922) is applied annually to combating alcoholism and diseases consequent, such as tuberculosis and venereal diseases, to subsidizing the establishment of teetotal inns, young people's clubs, and dairies, to instituting training courses for juvenile welfare workers and officers of philanthropic societies and to educational work (anti-alcoholic exhibitions, touring lectures, etc.). In addition to the State administrations the large private welfare associations also receive considerable financial assistance.

The pamphlet contains information on many other matters of interest, not only to public health officers, but to students of sociology in this country. The pamphlet for Austria contains even fuller details.

## Nova et Vetera.

### THE SALERNIAN RULES OF HEALTH

To wander through what were formerly the abodes of splendour or renown is always a melancholy proceeding, but in no case is this more true than in the case of the modern Salerno. Here is a sleepy Italian town of some forty thousand inhabitants. Few people move in the streets, and those few seem in no hurry about their business. Though the town has no natural attractions in itself, its situation at the head of a bay bearing its own name is exceedingly beautiful. From the sea the ground slopes upwards and reaches to the height of small mountains a short distance away. The oldest part of the town stands on high ground and still retains houses dating back to the twelfth, to the eleventh, and even, it is said, to the tenth centuries. Certainly the cathedral dates from the year 1070 and contains sarcophagi which may yet retain the mortal remains of the Norman adventurers who conquered Apulia in the eleventh century. We search in vain for any remains of the once famous medical schools or hospitals, "while memory watches o'er the sad review."

It was in 1075 that Duke Robert of Normandy, while leading the French and Normans to a crusade, arrived at Salerno and remained during the following winter. The crusade was successful, but the Duke, having received a wound, returned to Salerno to be cured. Either the cure was tedious or dalliance in love caused him to spend a whole year in the town, and this long absence abroad may have largely contributed to his loss of the English crown and to his twenty-eight years' imprisonment.

Though its renown as a centre of medical education has

long since gone, Salerno will remain famous by reason of the poem in rhyming Latin verse entitled "*Regimen Sanitatis Salernitanum*." This was composed in honour of Duke Robert and presented to him in 1076. It was esteemed so highly that no fewer than 100 manuscripts still exist, and over 240 printed editions appeared between 1480 and 1846.

It is really a treatise on all matters relating to the preservation of health (*Conseruandae Bonae Valetudinis Praecepta*), and though it contains the accumulated wisdom of the school the main part is thought to have been composed by John de Milano, who, indeed, in a manuscript of date 1418, is named as the author. It is written in a popular style, and in its original form was comparatively short, the edition of Arnould containing but 326 verses. Later writers have added to it to such an extent that the edition of M. Baudry de Balzac contains 2,300 verses, and that of Rienzi 3,520.

The following extracts have been made from the text of Arnould de Villa Nova, who lived close to Salerno in the thirteenth century, and it is this text which Sir Alexander Crooke published in 1830. It is much the same as that entitled "*Conseruandae Bonae Valetudinis Praecepta* longo Saluberrima Regi Anglorum quondam a Doctoribus Scholae Salernitanae. The Salerne schoole or the Regiment of Health. That is Physiell Observations for the perfect preserving of the Body of Man in Continuall Health. Edinburgh, printed by Andro Hart, and are to be sold at his shop, on the north side of the linc Street, a litle beneath the Crosso Anno domini 1613" (Black letter.)

The Salerno Schoole doth by these lines impart  
All health to England's King, and doth advise  
From care his head to keepe from wrath his heart,  
Drinke not much wine, sup light and soone arise  
When meat is gone long sitting breedeth smart  
And after noone still waking keep your cies  
When moov'd you finde your selfe to Nature's needs,  
Forbeare them not, for that much danger breeds

Use three Physicians still first Doctor Quiet,  
Next Doctor Merri man and Doctor Dret

Long sleep at afternoon breeds slouth, agues and rhumes

Great harmes have growne and maladies exceeding  
By leeping in a litle blast of wind  
So Cramps and Dropsies, Colicks, have their breeding  
And Mized brames, for want of vent behind  
Besides we find in stories worth the reading  
A certaine Romaine Emperour was so kind  
Claudius by name he made a proclamation,  
A seapo to be no losse of reputation

Pleares, apples, peaches milke and cheeso  
Salt-meats, Red Deere Hart, Beefe and Goat all these  
Are meates that breed ill blood and melancholy

Wine Women Baths, by Art or Nature warme,  
Usde or abuse, do men much good or harme

Six things that here in order shall insue  
Against all poison have a secret powre  
Peares Garlick Radish roots Nuts, Triacle, Rew  
But Garlick cheese, for they that it devoure  
May drinke, and eat not who their drinke do brew,  
May walk in aires infected every houre,  
With Garlick then hath power to save from death  
Beare with it though it make unsavoury breath  
And scorne not Garlick like to some that thinke  
It onely makes man winke, and drinke and stinke

Though all ill savours do not breed infection  
Yet sure Infection cometh most by smelling  
Who smelleth still perfum'd his complexion  
Is not perfum'd by *Poet Martialis* telling  
Yet for your lodging rooms give this direction  
In houses where you munde to make your dwelling,  
That nere the same there be no evil scents  
Of puddle waters or of excrements  
Let ayre be cleare, and light and free from faults  
That come of secret passages and vaults

If wine have overnight a surfet brought  
Then early in the morning drinke a draught  
And that a kind of remedy shall yield

(The poem then goes on to describe the kinds of wine and when they ought to be drunk.)

It in your drinke you mingle Rew with Sage  
All poyson is expell'd by power of those,  
And if you would withall lusts heat aswage  
Add to the same the gentle floure of Rose

Would not be sick when the seas do rage  
Sea water drinke with wine before he goes

Of washing of your hands much good doth rise,  
'Tis wholesome cleanly and relieves your eyes

Some to drinke onely water are assign'd  
But such by our consent shall drinke alone  
For water and small beere we make no question  
Are enemies to health and good digestion  
And Horace in a verse of his rehearces  
That water drinkers never make good verres

To show what liberties the translator has taken and how he has  
do additions both here and elsewhere, the original runs

Potus atque sumptus fit edendi valde necesse  
Infrigidat stomachumque cibum nititur fore crustum)

We see the better sort thereof [cheese] doth crite  
To make as it were a period of their meat  
The poorer sort when other meat is scant  
For hunger eat it to relieve their want

To close your stomach well this order sutes  
Cheese after Flesh Nuts after Fish or Fruits  
Yet some have said, beleeve them as you will  
One nut doth good two hurt, the third doth kill

Raw pears are heavy to digest we see  
Drink after Pears thies after Apples order  
To have a place to purge yourself of ordure

Cool damsons are good for health by reason  
They make your intestines soluble and slacke

By Figs are lice engendered, Iust provoked

New Rennish wine stirs urine doth not blude  
But rather loose the belly breeding wind

It [vinegar] makes one melanchol hurts their eyes,  
Not making fat nor mending their complexion  
It lessens sperme makes appetite to rise  
But taste and scent is good against infection

Four special virtues hath a rop in wine  
It maketh the teeth white it clears the eyne  
It adds unto an empty stomach fulnesse  
And from a stomach full it takes the dulnesse

Good dyet is a perfect way of curing  
And worthy much regard and health assuring

The wormes that knowes the wombo and never stint  
Are kill'd and purg'd and driven away with mint  
But who can write thy worth (O soveraigne worme)  
Some ask how men can do while thou dost grow

Rew is a noble hearbe to give it right  
To chew it fasting, it will purge the sight  
One qualitie thereof yet blame I must  
It makes man chaste and women fild with lust  
Fayre ladies, if these Physicke rules be true  
That Rew hath such strange qualites as these  
Eat little Rew lest your good husbands rew  
And breede betweene you both a sinew'd disease  
Rew whets the wit and move to pleasure you  
In water boyld it rids a roome of fleas

For writers old and new, both ours and forren  
Affirme the seed [of green willow] make women chaste and barren

If in your teeth you hap to be tormented  
By meane some little wormes therein do breed  
Which paine (if heed be tane) may be prevented  
By keeping cleane your teeth when as you feed  
Burne Frank incense (a gum not evil scented)  
Put henbane unto this and Onyon seed  
And with a Tunnell to the tooth that's hollow  
Convey the smoke thereof and ease shall follow

Four humours raigne within our bodies who's  
And these compared to foure elements  
The Sanguin Cholier Flegme and Melancholy  
The latter two are heavy dull of sense  
The other are more joviall quick and joly  
And may be likened thus (without offence)  
Lyke fire both warme and moist is Sanguin deare,  
Lyke fire doth Cholier hot and dry appeare  
Lyke water cold and moist is Flegmatique  
The Melancholy cold dry earth is like

The Sanguin gamesome is and nothing nyce,  
Loves wine and women and all recreation  
Lies pleasant tales and newes plays cards and dice  
Fit for all company and every fashon  
Though bold not apt to take offence nor usefull  
But bountiful and kind and looking chearefull  
Inclining to be fat and prone to laffer  
Loves mirth and musick, cares not what comes after

(The poem describes the characteristics of Cholier as being  
violent and fierce, ambitious, proud bountiful, often inebriate, a  
right bold speaker and 'as bold a lark' easily roused to anger,  
having a good appetite, 'yet ever looking pin'd')

In younger yeares they use to grow apace,  
In elder hairy on their breast and face

The Flegmatique Most of no great growth inclining rather to  
be fat and square lazy, not well educated, dreamy, or else still  
spitting to avoid the flegme

The Melancholy Very studious and solitary person apt to be  
hateful to others constant sometimes extreme in love, seldom  
in love, mistrusting, sparing, not daring

New though we give these humours severall names  
Yet all men are of all participant  
But all have not in quantity the same  
For some (in some) are more predominant

If Sanguin humor do too much abound  
These signs will be thereof appearing chiefe  
The face will swell, the cheeke grow red and round,  
With burning eyes the pulse beat soft and briefe  
The veins exceed, the belly will be bound  
The temples and the forehead full of griefe  
Unquiet sleepes that so strange dreames will make  
To cause one blush to tell when he doth wake  
Besides the moisture of the mouth and spittle  
Will taste too sweet and saure the throat to tickle

If Cholier do exceed as may sometime,  
Your eares will ring and make you to be wakeful  
Your tongue will seque all rough and oftentimes  
Cause vomit, unaccustomed and hatefull  
Great thirst, your excrements full of slime  
The stomach squeamish sustenance ungratefull  
Your appetite will sceme in nought delighting  
Your heart still grieved with continuall byting  
The pulse beat hard and swift all hot extreme  
Your spittle sowie, of firewore oft your dreames

If Flegme aboundance have due limits past  
These signes are here set downe will plainly shew  
The mouth will sceme to you quite out of taste  
And apt with moisture still to overflow  
Your sides will sceme all sore down to the waste,  
Your meat war lothsome, your digestion slow  
Your head and stomach both in so ill taking,  
One reeking ever gipping t'other raking  
With empty veins the pulse beat slow and soft  
In sleep, of Seas and Rivers dreaming off

But if that dangerous humor over raigne  
Of Melancholy sometime making mad  
These tokens then will be appearing plaine  
The pulse beat hard the colour darke and bad  
The water thin a worke fantastick biane  
Ialse grounded joy or els perpetuall sad  
Affrighted oftentimes with dreames like visions  
Presenting to the thought all apparitions  
Of bitter helches from the stomach coming  
His crye (the left especiall) ever burning

To bleed doth cheere the pensive and remove  
The raging furies bred by burning love

Make your incision large and not too deepe  
That blood have speedy issue with the fume  
So that from sinnewes you all hurt do keepe  
Nor may you (as I taught before) presume  
In sixe ensuing houres at all to sleepe  
Lest some slight blisse in sleepe cause an apostume

First in the Spring for quantity you shall  
Of blood take twyce as much as in the Fall

In Spring and Summer let the Right Arme blood,  
The Left and Winter for the left are good  
The Heart and Liver Spring and Summer bleeding  
The Left and Winter hand and foot doth mend  
One vein cut in the hand doth helpe exceeding  
Unto the spleene voyce breast and intrals lend  
And swages griefes that in the heart are bleeding

#### The Translator to the Reader

But here the Salerne school doth make an end  
And here I cease to write but will not cease  
To wish you live in health and out in peace  
And ye our Physick rules that frindly read  
God grant that Physick you may never neede

These few extracts will show the scope and intention of  
the poem and that it was well suited to the needs of the  
time in which it was written is evident

## CANCER RESEARCHES

INVESTIGATIONS into the biochemical properties of the blood serum in disease, especially when they come to fruition and prove to be of practical service in diagnosis, are of interest to all clinicians. While still in the imperfect stage they are of even greater interest to laboratory workers, who may by their experiments and criticism develop a more finished and certain technique than had been foreseen by the individual who began the work. On the other hand, the play of instructed criticism may prevent the adoption into practical medicine of a jejune or a fallacious method. The sero diagnostic methods in cancer have been numerous and varied, but none so far has satisfactorily passed the test of reliability. Remembering the many attempts in the past, with their claims pitched high and their accomplishments so disappointing, we approach each new reaction with increasing scepticism if only it would exhibit a human amount of fallibility we should bid it a kinder welcome. Probably in most cases the organisms are aware of the clinical diagnosis before recording the results of their reactions (indeed, in working out the method this must be so at the beginning), and unconsciously they are biased in their interpretations, smoothing out the doubtful findings and dismissing or excusing the palpably adverse. The critical student, unimpressed by the reputed perfections of another's bantling, emphasizes the failures. Not infrequently, too, the number of cases tested or recorded is much too small, or the sample of other diseases is too selected for the real worth of the reaction in practice to be estimated. Now and again a method is propounded which, from internal evidence, impresses the reader as worthy of trial.

We publish this week (p. 4) a communication by Dr. H. J. B. Fry of the Cancer Hospital Research Institute giving details of a sero diagnostic method of his own devising which seems to have been sufficiently well tested to be put before the critics, and for which the claims are modestly stated. It is a simple flocculation reaction that apparently gives sharp readings. The "antigens" (why cannot pathologists agree to use a more accurate designation?) have been prepared from mammary carcinomata, and are composed of the alcohol soluble constituents of the material from which substances soluble in saline and acetone have previously been removed. The alcoholic extract, fortified with cholesterol, is standardized and added to four dilutions of the inactivated serum under test. The tubes are incubated, and a preliminary reading is taken at the end of three hours, the final result being determined after twenty-four hours at room temperature. A positive result is indicated by the appearance of flocculi in the tubes. In a series of 500 cases, comprising malignant and non-malignant conditions, 75 per cent of correct results were obtained, positive results were obtained in 71 per cent of the cancer cases, and negative results in 78 per cent of the non-cancerous, while the serums of healthy individuals in all but one instance reacted negatively. The analysis of the results is interesting.

There are two rather surprising findings in the use of this method. Seeing that the "antigen," at least in its mode of preparation, so closely resembles that of Boidet and Ruelens used in the flocculation reaction for syphilis, it might have been imagined that syphilitic serum would be apt to give positive reactions, but when tested in parallel with the Wassermann reaction Dr. Fry's reaction did not seem to be sensitive in this respect. The latter depends on some other reacting substance present in the serum. The other unexpected feature is that the antigens prepared from the epithelial cell carcinomata of the breast reacted even better with serums from other malignant manifestations than they did with the serums of patients suffering from mammary cancer. In fact, a very low percentage of successes (58) was given by breast cancers, while epitheliomata, as of the skin, oesophagus, bladder, and cervix uteri, showed from 80 to 100 per cent of positive results. The antigen also gave satisfactory results with the serum from cases of sarcoma. Taking all the cases of malignant disease together, the results of this reaction are as good as those obtained by means of the Wassermann reaction in all cases of untreated syphilis. So much for the positive side. On the other hand, the reaction proved fallacious in about 20 per cent of the non-cancerous cases. Perhaps this figure is unduly high, for Dr. Fry has considered as non-cancerous all those cases in which a diagnosis of malignancy could not be established. The sensitivity of the reaction with tuberculous serums, in particular, is unfortunate, but, excluding this disease, the results of the reaction are very promising, and would seem to be very helpful in the diagnosis of clinically doubtful conditions. The further exploration of this reaction by Dr. Fry and others will be welcomed.

Another member of the staff of the Cancer Hospital Research Institute, Dr. E. L. Kennaway, contributes to our columns this week (p. 1) an important paper bearing on the problems of the etiology of cancer. He had previously<sup>1</sup> investigated various fractions of coal tar and compounds derived from tar in order to throw light on the chemical constitution of the cancer-producing factor. The finding of such a substance would have been much more than a mere laboratory triumph, for it might have afforded an insight into the unknown substances which, it must be supposed, are responsible for the induction of malignant processes in general; whether we admit that their function is exciting or merely predisposing. The analysis of coal tar, however, having proved disappointing in this respect, Dr. Kennaway has approached the problem from another aspect. From such compounds of known chemical constitution as isoprene and acetylene he has been able to prepare tar-like products of comparatively simple composition, containing no elements other than carbon and hydrogen, which have proved particularly effective in producing epithelioma when applied to mice. The influence of high temperatures on the formation of carcinogenic substances from coal and petroleum, so important industrially, led him to try if similar substances could be produced from previously living tissues. A tar prepared from yeast had the cancer-producing property. A distillation product from human skin also exhibited the same property. It is obvious that in the living body there cannot be such a crude process in action to produce from the tissues this carcinogenic substance, but it is not beyond the bounds of possibility that

<sup>1</sup> BRITISH MEDICAL JOURNAL, March 29th 1924, p. 564.

"the human skin may be capable of forming very slowly substances which, when required in bulk and rapidly, can *in vitro* be produced from skin only at a red heat" The hydrolysis and oxidation of fats and proteins which take place in the body can only be performed in the laboratory by strong reagents and high temperatures. In discussing the results he has obtained in these interesting researches Dr Kennaway dissents from the views of some critics that the carcinogenic agents, as established by the experiments at the Cancer Hospital, merely act because they are "irritants." There are irritants and irritants some may produce cancer, while many do not. The property of producing cancer is a special property, whether a substance possesses it or not cannot be determined from a knowledge of its chemical constitution or its immediate effect on tissues, but only from the slow, unintentional mass experiment on human beings, or, more directly and speedily, by the set experiment on lower animals.

### CLASSIFICATION OF BACTERIA

ALL bacteriologists will agree that the time has come when more serious effort should be made to classify bacteria in a scientific way, but the difficulties of the task are enormous. The earlier classifications, based primarily on morphology, have proved unsatisfactory. Later, when the botanist stepped in to catalogue these tiny members of his extended kingdom, he neglected the physiological behaviour of too many of them, with the result that his cumbersome Latin titles found no favour with the practical bacteriologist. Meanwhile the philistine pathologist has been a flagrant offender in the eyes of the systematic biologist, because he has simply named his germ according to the disease it produces, and neglected the conventions of both botanists and zoologists. As a rule the biologist has only been interested in the bacillus and the pathologist in the disease.

We have been watching with great interest the labours the Society of American Bacteriologists has undertaken with the object of deciding on some acceptable system of classification. In September, 1917, appeared the preliminary report of the committee, presided over by Dr Winslow, on characterization and classification of bacterial types, and in May, 1920, the final report of the committee was published. In 1923 a committee of the same society prepared a manual of determinative bacteriology, which in general followed the classification suggested by Winslow and his colleagues. These publications constitute a notable advance, and should do a great deal to produce order out of the prevailing chaos.

We welcome a further contribution to the same subject from Dr R. E. Buchanan, professor of bacteriology at the Iowa State College.<sup>1</sup> He has written the first of a series of monographs on systematic bacteriology, to be published by the Society of American Bacteriologists. This is a book of close on 600 pages, devoted to the history of the nomenclature and classification of the groups of bacteria hitherto described. The first chapter is an historical account of the various classifications of bacteria that have been proposed. Thence he passes, in the second chapter, to a discussion of codes of nomenclature and their relation to the problems of bacterial terminology. The third and final chapter, which constitutes nearly

two thirds of the book, contains an alphabetical list of the names which have been proposed for subgenera, genera, subtribes, tribes, subfamilies, families, orders, and classes of bacteria, including casual or vernacular terms which have had more or less extensive recognition. Professor Buchanan has attempted with each name to give the original diagnosis of the term, to discuss its usage by bacteriologists, and to point out whether or not its use is legitimate. Wherever practicable the author has quoted the original description and discussed the comments of subsequent writers. Obviously the compilation of such a dictionary as this has necessitated an immense amount of study, and there is no doubt that it will be extremely useful as a guide to correct nomenclature.

### CENTENARY OF THE HOUSE OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON

FOUNDED by Thomas Linacre in 1518, and therefore now in its fifth century, the Royal College of Physicians of London has had four homes, three of them close together in the neighbourhood of St Pauls—in Knightbridge Street (1518-1614), in Amen Corner (1614-1666), destroyed by the Great Fire, and in Warwick Lane (1674-1825). Its move in 1825 had been foreshadowed for some time by the alteration in the character of the neighbourhood, which had become "the wrong end of the town," and by the deterioration of the building. In 1814 the College petitioned for, and succeeded in obtaining from Parliament, an Act to allow it to hold its meetings and exercise its powers within the City of Westminster. But the really effective influence in bringing about the removal was that of Sir Henry Hallford, who was elected President at the early age of 54 in 1820 and remained in the chair for the univalled term of twenty-four years—in fact until his death in 1844. He was physician in ordinary to four sovereigns, and through his personal influence with George IV and the Prime Minister, the Earl of Liverpool, was largely responsible for the grant on the present site of the College in Pall Mall East, then valued at £6,000, for ninety-nine and a half years, this was extended in 1864, during the presidency of Sir Thomas Watson, by an Act of Parliament to nine hundred and ninety-nine years. The architect of the present house, Sir Robert Smirke, R.A., also designed the British Museum, the General Post Office in St Martin's le Grand, and numerous other well known buildings. In 1822, while the new College—which with its fittings cost £25,000—was being erected, George IV showed his appreciation of the character and abilities of Sir Henry Hallford by declining that every future President of the College should for the time being hold the office of physician in ordinary to the King. But this high honour to the College apparently lapsed, for the next President (1844-56), Dr John Aitken Paris, did not receive any Court appointment to Queen Victoria. At 3 p.m. on June 25th, 1825, there was a grand ceremonial opening of the new College, attended by no fewer than five dukes of the blood royal and many other distinguished personages, Sir Henry Hallford, wearing the decoration of the Royal Guelphic Order (K.C.H.) conferred on him that morning, delivered an eloquent inaugural oration in Latin to the three hundred auditors, who were subsequently entertained at a sumptuous collation until about 5 p.m., when the President and some fifty of the ninety-one Fellows solemnly retired to the library to hold the Comitia Majora. The centenary of this opening was celebrated at the College on the night of June 25th, 1925, by a *conversazione*, arranged by the Treasurer, Dr S. Phillips, and attended by some four hundred of the Fellows, Members, and guests, including ladies and some of Sir Henry Hallford's descendants.

<sup>1</sup> *General Systematic Bacteriology*. By R. E. Buchanan. Ph.D. Monographs on Systematic Bacteriology. Baltimore: Williams and Wilkins Co. London: Baillière Tindall and Co. 1925. (Roy. Bro. pp. 597)

The guests were received in the library by Sir Humphry and Lady Rolleston. It is a fine room, and in it are hung some of the most precious of the College portraits—those of William Harvey (by Janssen), Radcliffe (Godfrey Kneller), and Sir Thomas Watson, prints were on view in two rooms, and by the generosity of Lord Ashfield of Southwell three cinematograph shows of nature films were given in the lecture room. The censor's room, the handsome panelling of which dates from 1674, when the house in Warwick Lane was built, contains the fine portraits of Richard Warren (Grimsborough), Linacre, Thomas Sydenham, Sir Samuel Grith, William Heberden the elder, of the *Commentaries*, whom Samuel Johnson called "Ultimus Romanorum, the last of the learned Physicians," Sir George Baker, and of other well known physicians. Altogether the College possesses one hundred and twelve portraits in oils and six thousand engravings of physicians, they have recently been catalogued by the Huxleyan Laboratory, Dr Arnold Clapham—a labour of love, but nevertheless a very onerous task. The walls of the reading room on the ground floor also carry a number of fine portraits, especially the full-length presentments of Sir Henry Hallford (Thomas Lawrence), Sir William Jenner, and Sir Richard Quain. The library, of about forty thousand volumes is particularly rich in old books, more than four thousand dating from before 1600, of these about one hundred were rescued from the College when burnt down in the Great Fire of London. Much interesting information of a personal and even gossip character is given in *The Gold-headed Cane*, written by Dr William Macemichael and published anonymously in 1827. A second edition appeared in the following year. It was supposed to be the reminiscences of the cane carried successively by Radcliffe, Mead, Astle, Pitcairne, and Matthew Baillie. In 1884 Dr William Munk published a much expanded edition carrying the story down to 1858. All these editions are now rather difficult to pick up. In 1915 there appeared from the publishing house of P. B. Hoeber (New York) a fourth edition, with an introduction by Sir William Osler and a preface by Dr Francis R. Packard, the editor of the *Annals of Medical History*, thus, like the fifth edition in 1923, with an introduction and annotations by Dr G. C. Percher, reproduced the text of Macemichael's second. The gold-headed cane, one of the curiosities of the College, reposes, with Harvey's dissecting pointer and other interesting relics, in a case in the large library. The exterior of the College has now, to match the adjoining Canada House opened by the King and Queen on Monday, put on creamy white in place of the sombre hue that has characterized it for many a long year.

#### WOMEN'S WAR MEMORIAL

THE FIVE SISTERS WINDOW in York Minster is one of the most famous in Christendom, there is nothing quite like it anywhere else—nothing, at any rate, on the grand scale. The architect must have been a bold man. The window of five lancet lights occupies practically the whole of the end of the lofty north transept, soaring without tracery in austere simplicity to the roof, the middle light is the highest, the others dropping with the curve of the rich York is not rich in stained glass, and the visitor is constantly drawn back to the crossing of the nave from which the great window is best seen. It is in grisaille—that is, the general effect is a pattern in grey with a few spots of colour. It looks like transparent tapestry, and the story is that five sisters in the thirteenth century embroidered the design. The window had got into rather bad condition, and had been glazed outside, thus the amount of light passing through was diminished. The menace of German bombs

caused it to be taken down, it was then seen that both the glass and the lead mouldings were in bad condition. At this stage the idea occurred to Mrs. Little, a lady residing in York, of inducing women to collect money enough to put it in order as a memorial to women who gave their lives in the war. The appeal was immediately successful, the £3,000 required was received within nine weeks, and enough came in afterwards to pay the cost of an oak screen bearing a roll of honour containing the names. It has been placed in the St. Nicholas Chapel near the window, and has twelve panels bearing altogether 1,400 names. One panel contains the names of the medical women—Laura Foster, Elsie Impey, Sybil Lewis, Isobel Tate, Marion Wilson, Elsie Inglis, and Louisa Woodcock. Each panel is covered by a door, and that to the medical women bears the emblem of the medical profession—the rough stick with the twisted serpent—made from a drawing of the emblem designed for the Gates of Honour the British Medical Association has just put up at the new house. The owner of Rievaulx Abbey, in northern Yorkshire, gave the lead for the restoration, it, therefore, is also of the thirteenth century. All the work was done in the Minster workshops, and the reinstated window was unveiled by the Duchess of York on June 24th. Deputations from all branches of women's war services were present in uniform, and the medical members in academic dress. A procession was formed, which passed through the streets, lined by civilians and thousands of spectators, to the Minster, where a short religious service was held. Representatives were present from the Dominions also from the Home Office, the India Office, the Air Ministry, the Royal Navy, the Army Council, the mercantile marine, Queen Alexandra's Royal Naval Nursing Service, Queen Alexandra's Imperial Military Nursing Service, the Territorial Force Nursing Service, Princess Mary's Royal Air Force Nursing Service, Joint Committee of the British Red Cross and Order of St. John of Jerusalem, Queen Mary's Army Auxiliary Corps, Women's Royal Naval Service, Women's Royal Air Force, Women's Foreign Corps, Women's Land Army, Scottish Women's Hospitals, Friends' War Victims Relief Committee, and Serbian Relief Fund. Miss Frances Evans, M.S., M.B. Lond., who had charge of the French hospital at Abbeville Royumont during the war, represented the Medical Women's Federation. At the same time as the ceremonial was taking place in York, commemoration services were being held in South Africa, South and West Australia, Tasmania, New Zealand, and Canada. The knowledge that these services were taking place made the words of the Archbishop in his address particularly true—"The emotion which unites us here is, as it were, a beating of the Empire's heart."

#### THE CIVIL RESEARCH COMMITTEE

A STATEMENT was made about the functions of the new Committee of Civil Research in a Treasury minute issued last week. It stated that the president of the Committee will be the Prime Minister and the regular chairman to act in his absence a Minister nominated by him. The members of the Committee will be such persons as are summoned by the Prime Minister or the chairman. It is modelled on the Committee of Imperial Defence, and, like it, will be an advisory body without administrative or executive functions. Its duty will be to give connected forethought from a central standpoint to the development of economic, scientific, and statistical research in relation to civil policy and administration, and it will define new directions in which inquiry would be valuable within these limits. The Committee will consider such questions as are referred to it by the Cabinet, the president, the chairman, and Government departments, and the president or chairman may summon for consideration of particular business

such outside economic, scientific, or statistical experts as he may think fit. It will be authorized to refer particular inquiries to special subcommittees, which may include outside specialists as well as expert officers of the department or department concerned. Departmental officers may be appointed to act as secretaries of such subcommittees. The scheme has been approved by the Treasury. The Earl of Balfour (Lord President of the Council), in reply to a question by Viscount Haldane in the House of Lords on Tuesday, said that the Committee was an additional wheel required to complete the mechanism of Cabinet government, but would not substantially modify that government. He specified three directions in which its assistance would be immediately available: it would deal with matters which concerned more than one department, with matters which, though they concerned only one department, were abnormal and raised problems of unrecustomed magnitude with which the fixed organization of the department was not well capable of dealing, and it would afford a convenient method by which the Dominions could be called into counsel at their desire if any question were raised in which they were specially interested. The defects of the existing machinery of government could not be cured by any other method. Royal Commissions conducted important investigations, but their functions were not conducive to rapid administrative action, especially because they had fixed references from which they could not depart, and lacked continuity. If the new Committee was to work well it must be with the full assent and co-operation of existing departments. The Committee would not be entitled to dictate in the smallest degree to any Minister or any Ministerial department, but it would serve to bring departments together to deal with problems no department was capable of dealing with alone.

#### ROYAL MEDICAL BENEVOLENT FUND

THE eighty-ninth annual report of the Royal Medical Benevolent Fund, for the year 1924, is a document we have studied with mingled feelings. On the one hand, we find a record of unselfish and devoted work on the part of a few of our colleagues. On the other hand, it is scarcely a credit to our profession that the income of a charity of this kind should be considerably less than £10,000. It is true that the Fund is rather better supported than it was forty years ago. Thus in 1884 there were 25,321 names on the *Medical Register*, and the income of the Fund was £3,068, in 1924 registered practitioners numbered 49,958, and the income was £9,189. Nevertheless, while the demands on the Fund increase steadily every year, the income grows very slowly, nearly half of it is derived from invested property, subscriptions and donations amounting only to £4,846. While the Committee of Management is able to record an increase of £1,000 in new subscriptions, old subscriptions fell off, from death and other causes, by the same sum. The amount expended in grants (numbering 343) was £5,001, and in annuities (numbering 147) £3,467, the working expenses were £1,254. All current subscriptions and donations are paid into the grant account, out of this the monthly grants are made with which our readers are familiar from the summaries of sad cases which appear from time to time in the columns of the *BRITISH MEDICAL JOURNAL*. Not only do the applications for help become more numerous each year, but the increase in the cost of living makes it necessary to give larger grants than formerly whenever possible. The amount of hardship and even starvation of which many of the older applicants complain is so distressing "that if it could only be made better known to the profession, there would at once be a large wave of benevolence, which would pour money into the funds of the society." Among the ways in which

further support has been sought of late years is the sending out of a letter written by a vice-president or a local secretary and reproduced in facsimile, another is the posting of reminders to those whose subscriptions have lapsed for some time. Acknowledgement is made in the report of the great assistance rendered to the Fund by the British Medical Association in the collection of subscriptions. During 1924 the Association forwarded £1,110, being an increase of £200 on the amount collected in the previous year. A gift of £210 from the Medical Insurance Agency is gratefully acknowledged, and in this connection the Committee of Management places on record its regret at the death of one of its members—Dr G. E. Huship, late Treasurer of the British Medical Association, who was instrumental in obtaining liberal grants to the Fund from the Agency, of which he was chairman for fifteen years. The report includes some account of the work of the Guild, or Ladies' branch of the Fund, which renders invaluable help, it has district representatives who get into personal contact with the grantees, and are able to advise about gifts of comforts in the shape of special foods, clothes, and coals. In a great number of cases, especially where there are children to be educated, the two funds work together, and constant and close co-operation is maintained between them. We commend the Fund and the Guild to the sympathetic notice of all our readers.

#### THE CONSERVATIVE TREATMENT OF ECLAMPSIA

THOUGH there is still some disagreement about the details of the treatment of eclampsia, it appears to be generally agreed that conservative measures are superior to such radical procedures as delivery by high forceps, forcible dilatation of the cervix, and vaginal Caesarian section. Last July Professor Stroganoff of Leningrad presented a paper to the Royal Society of Medicine which included an account of the special chloral treatment associated with his name, it was reported in our issue of July 12th, 1924 (p. 53). Three articles on this subject have now been published in the *American Journal of Obstetrics and Gynecology* for March, 1925. Dr H. J. Stander, who has studied the Stroganoff method in Leningrad, discusses this treatment in detail, and points out two steps in the method which appear to him irrational. He believes that chloroform used in the small quantity stipulated by Stroganoff cannot produce a satisfactory narcosis, and the possibility of chloroform poisoning is a further argument against its use. Dr Stander does not agree with Professor Stroganoff that venesection of 200 to 300 c.c. (7 to 11 fl. oz.) will be of any material value in the lowering of the blood pressure or in eliminating toxins, and holds that it should not be employed at all, or alternatively that larger quantities of blood should be withdrawn up to as much as 1,000 c.c. (35 fl. oz.). Dr E. Speidel compares the Stroganoff method with the treatment advocated at the Rotunda Hospital in Dublin, the McPherson system, and the use of veratrum viride. He suggests that the value of veratrum treatment may have been discounted unduly because too small a dose has been given, and states that Dr Gillespie advises that in antepartum eclampsia 60 minims of veratrine—a standardized preparation of veratrum—should be injected hypodermically as the initial dose, and followed by doses of 15 minims every ten minutes, until there is sighing respiration, copious bilious vomiting, and a soft pulse with a rate of 40 to 60. No other advocate of this remedy appears to have recommended such heroic doses. The treatment recommended by Dr Ross McPherson resembles both the Rotunda and Stroganoff methods to some extent, but he depends entirely upon morphine for the narcosis. Dr Speidel, after trying this method for two years, was disappointed with the

results, the maternal mortality being high and the morphine tending to check elimination by the bowels and to produce pulmonary complications, in spite of the simultaneous administration of atropine. He found, moreover, that the morphine was insufficient as a narcotic, and that manipulations incited convulsions. Dr. Speidel, therefore, favours the Rotunda method, and suggests that reports by the larger maternity hospitals on the systems they employ should be collected annually in order to reach some definite conclusion with regard to the treatment of eclampsia. He considers that every hospital ought to establish a definite routine of treatment so that no time may be lost in dealing with any case. His other recommendations include the following: The eclamptic patient should be treated in a well lit room (not a darkened room, as recommended by Professor Stroganoff), she should lie on her side, with her head low and near the edge of the bed, particular care being taken to prevent the aspiration of secretion into the lungs. No anaesthetics should be used during the convulsions, but the administration of oxygen and nitrous oxide is advised as a preventive measure during manipulations. A hot wet pack, together with the uniform and continuous warmth obtainable by the use of an electrically heated blanket, will secure relaxation and hasten delivery. Venesection to the extent of 500 ccm (nearly one pint) followed by the introduction of 500 ccm of 10 per cent glucose solution, should be employed if the blood pressure is above 150 mm Hg and convulsions continue. Dr. C. L. King recommends the use of morphine, 1/2 grain being given to the patient on admission. Venesection to the extent of 500 to 800 ccm follows, the blood pressure being carefully watched and the procedure discontinued immediately it falls to 130 mm. If only a small amount of blood has been withdrawn and the convulsions have not been checked, this procedure is repeated. Dr. King reports that, as a rule, convulsions cease after this treatment, but if they do not 1/4 grain of morphine is given. He has employed 1 grain or more without harmful effects, and sometimes he uses in addition chloral hydrate and potassium bromide. The stomach and the colon are washed out subsequently. Under this treatment he reports that there has been no maternal mortality. Should labour begin during the treatment it is permitted to continue naturally, if it does not begin he thinks it should be induced, but generally not until convulsions have ceased and the patient's condition has improved.

### THE HEATING OF LIVING ROOMS

THE Fuel Research Board of the Department of Scientific and Industrial Research has just issued a "technical paper" on the heating of rooms, and we have fortunately been able to induce Dr. Fraser Harris to study it for us. It is, he writes, a very good example of the investigation of a familiar, everyday problem by the combined methods of physics, mathematics, and physiology. The object of the research was to ascertain and express in scientific terms the conditions making for comfort indoors when the sources of heat were respectively coal, coke, gas, and electricity. Even "comfort" is a relative term, here it means comfort to one whose occupation is sedentary for several hours together. The observations were carried out in the Westminster Technical Institute. The paper opens with a succinct account of the physiology of the production and the loss of animal heat, and calorimetry generally. The equipment of the experimental room is fully described, as well as are the methods for measuring such variables as

air temperatures, wall and floor temperatures, velocities of draughts, and the total volume of air passing through the room in a unit of time. Radiation from the source of heat was measured in absolute units by a Richmond radiometer and by a Bone-Callander-Lates volometer. British thermal units were used. The distinction is clearly drawn between heating by radiation and heating by convection (heating of air), a subject about which there is a great deal of popular confusion. The experimental room received no direct sunlight, and therefore no heat of solar origin. All factors were investigated: the sizes of the rooms (1,000, 2,000, and 4,000 cubic feet), the number of persons (from one to six), the distances from the source of heat at which the occupants experienced comfort or the reverse ("zones of comfort"), and the relative humidity. Some interesting figures are given in comparing the proportion of heat received by the room with the total potential heat of the fuel or source. This ratio is called the "efficiency", thus, with the open coal fire from 17.5 to 25 per cent of the total heat-energy reaches the room as radiated heat, and 5 per cent more is received in convected air, making a total of from 22.5 to 30 per cent "efficiency", the rest (from 77.5 to 70 per cent) is lost up the chimney. The total efficiency of a modern gas fire is about 55 to 60 per cent—45 to 50 per cent by radiation and 10 per cent by convection. The total efficiency of an electric heater is 100 per cent, 70 per cent of this is radiated and 30 per cent convected. The efficiency of a "radiator" system (hot-water coils) is about 50 per cent. The various factors involved in the problem are stated so admirably that we may quote the paragraph: "The rate at which heat must be delivered to a room in order that its temperature may be maintained at a constant level depends upon the size, construction, and position of the room and upon the external weather conditions. When the heat is first turned on to a room in cold weather there is a gradual rise in the temperature of the air and fabric of the room, the total heat capacity usually being so great that a steady state is not attained for some days. When a steady state is reached, and there is no further rise in temperature of the structure, the amount of heat delivered to the room must be exactly balanced by the amount flowing out by conduction through the walls, floor, ceiling, windows, etc., together with that carried away by the air which passes through the room." The paper contains thirteen tables of statistics and six diagrams (curves). Table XIII is one of the most interesting: it shows the cost in pence for a sixteen hour day to heat by radiation rooms of the three different sizes, and with from one to six occupants, by means of the open coal fire, the open low-temperature coke fire, the open gas fire, and the electric heater. In commenting on this table it is remarked that "for continuous heating by far the cheapest means of providing radiation is an open fire of low-temperature coke, open coal fires are slightly more expensive, gas fires are about 2½ times as dear as coal, and electric heaters are 5½ times as dear as coal." The whole investigation, although carried out on lines of such scientific accuracy, is exceedingly practical, as one of the concluding sentences testifies: "Whatever the method of heating adopted, the cost will be closely allied with the completeness of the insulation of the rooms, and it is of the greatest importance to construct houses in such a way as to avoid high conduction losses." Builders, we fear, give very little heed to this principle in the construction of walls. An air space between two thicknesses of brick and double windows are two practical suggestions made. The pronouncement on hot-water radiators is valuable: "It will be seen that at 50 per cent efficiency hot-water radiators prove to be the cheapest method of heating continuously a 1,000 cubic foot room, but that for a 4,000 cubic foot room an open low-temperature coke or coal fire is cheapest

<sup>1</sup> Department of Scientific and Industrial Research. Fuel Research Board. Technical paper No. 12. The Heating of Rooms: a Comparison of the Costs of Different Methods on the Basis of Warmth Comfort. By Margaret Fishenden D.Sc. assisted by R. E. Willgren B.Sc. London. H.M. Stationery Office. Price 1s. net.

until there are more than three people in the room, when hot-water radiators again become the most economical." In an investigation of so exhaustive a character we would have expected some reference to the method of heating by hot-water piping the walls and ceilings of large buildings known as the "panel system," examples of which are to be found in Bush House, Kingsway, and in Austria House in the Strand. Similarly, the method adopted in Liverpool Cathedral, which is practically a return to the Roman method of heating the floors by means of hot air, might also have been alluded to, particularly since this method attracted so much attention in the press in the autumn of 1924. The data are all given in British units and the decimal system is not used, which will make comparison of the statistics with those of Continental works somewhat troublesome. There is a full bibliography and an excellent index, which occupies no less than four pages out of a total of forty-eight pages for the entire monograph.

#### AN INTERNATIONAL HEALTH CONGRESS

As travelling facilities increase the world grows smaller and more convenient for congresses and conferences, that is being discovered by all classes of the community, and questions which were at one time no more than national have become international, whether the objects are health, politics, religion, labour, or revolution. At the same time, owing to the great war, an enormous share of such wealth as has not been destroyed has been transferred from the Old world to the New, and the idealism which finds so congenial a field in America has opportunity for expressing itself in ways which make for the welfare of mankind. A recent example is to be found in the action of the United Fruit Company, whose headquarters appear to be at Boston, Massachusetts, though its activities must be mainly elsewhere. In 1923 it held a round table conference of nine medical superintendents of its hospitals in Central America. It is claimed, indeed, that the company has transformed great tracts of jungle into fertile and wholesome garden lands, has carried civilization into the tropics, and has been a pioneer in looking after the health and welfare of many thousand employees. The conference of 1923 decided that there should be a larger gathering, and invitations were issued to eminent workers in tropical medicine in the four quarters of the globe to meet at Kingston, Jamaica, on July 22nd, 1924, after the conference finished its work (on August 1st) the members were given opportunity to inspect the health activities of the company in Honduras, Panama, and elsewhere. The proceedings of the gathering at Kingston have been issued in a large and handsome volume,<sup>1</sup> with a preface by Professor M. I. Rosenau of the Harvard Medical School. The contributors from this country included Sir Arbuthnot Lane, Sir Leonard Rogers, Sir James Fowler, Sir Arthur Newsholme, Sir Thomas Oliver, Dr Arthur E. Horn, Professor John W. Stephens, and Dr John G. Thomson. Dr Bunting was present from Toronto, and many other well known authorities. Some seventy papers were read, mostly on subjects of great importance. We do not propose to attempt to give any account of the contents of the thousand pages of *Proceedings*, the striking fact is that such a meeting was held. The United Fruit Company is to be congratulated on the way in which it organized the conference. The volume of *Proceedings*, well printed and well illustrated, is defective in that while it has a table of contents there is no index, so that it will be very difficult to use it for reference on particular points as to which it ought to be available for ready consultation. Otherwise there can be nothing but praise for the enterprise and its outcome.

<sup>1</sup> *Proceedings of the International Conference on Health Problems in Tropical America*. Boston, Massachusetts: United Fruit Company, 1924. (Med. 8vo pp xii + 1010. 16 plates.)

#### THE SECRETARYSHIP OF THE ROYAL SOCIETY OF MEDICINE.

THE Royal Society of Medicine has decided to mark Sir John MacAlister's retirement from the office of secretary, which took effect on July 1st, by appealing for funds to raise a memorial to his great work for the society. What this work has been has already been summarized in our columns. It is anticipated that his numerous friends will gladly contribute, and that Fellows of the society will be anxious to see a permanent memorial of the man to whom the existence of their institution is chiefly due. It is hoped that the memorial will take the form of some portrait in oil or stone. At its last meeting the council selected, from a very large number of applicants, Mr. Geoffrey R. Edwards, B.A. Cantab., to succeed Sir John MacAlister as secretary. Mr. Edwards was educated at St. Paul's School and St. John's College, Cambridge. He studied in Germany to qualify for the Woods and Forests Department of the Indian Civil Service. On his return from India he joined the Royal Air Force as a pilot. While up on active service he was wounded and had to fight in the enemy's country, and was imprisoned in Germany for fourteen months. Subsequently he served on the Repatriation Commission in Germany and on the Inter Allied Aeronautical Commission of Control. On demobilization he was appointed assistant secretary to the National Physical Laboratory, Teddington, where he has had considerable experience in library and editorial work and in organization. He takes up his duties on September 1st.

#### LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

In order to obtain designs for the permanent quarters of the London School of Hygiene and Tropical Medicine to be erected on the site adjoining Keppel Street, Gower Street, and Malet Street, near the British Museum, the board of management of the school in December last instituted a competition limited to five architects who had specialized in the planning and equipment of the type of building required, and appointed Sir Frank Brines, Director of Works at H.M. Office of Works, as assessor. The board, under the chairmanship of the Right Hon. Sir Alfred Mond, M.P., has now unanimously adopted the assessor's award in favour of the design submitted by Mr. P. Morley Holder, and he will be appointed architect for the new building. It will be remembered that the funds for the erection of the new building are being provided by the Trustees of the Rockefeller Foundation, who offered the British Government nearly half a million sterling for site, building, and equipment.

We greatly regret to announce the death, on June 27th, as the result of a motor-car accident, of Mr. Hamilton Drummond, F.R.C.S. Ed., assistant surgeon to the Royal Victoria Infirmary, Newcastle-on-Tyne, and a son of Sir David Drummond, formerly President of the British Medical Association. We hope to publish a memoir in an early issue.

THE Committee of the Royal College of Physicians of London and the Royal College of Surgeons of England is about to appoint a Stierfeld Research Scholar. The emolument will probably be £250 per annum and the tenure three years, at the discretion of the Committee. Applications stating the nature of the proposed research should be sent to the Registrar, Royal College of Physicians of London, Pall Mall East, S.W. 1, not later than October 1st. Further particulars will be found in our advertisement columns.

# NINETY-THIRD ANNUAL MEETING of the British Medical Association, BATH, 1925

Doorway of St John's Hospital (From a wood engraving by Horace Gerrard)

THE ninety-third Annual Meeting of the British Medical Association will be held at Bath at the close of this month, under the presidency of Dr F G Thomson, physician to the Royal United Hospital, Bath, and consulting physician to the Royal Mineral Water Hospital. The Annual Representative Meeting will open in the Concert Hall of the Pump Room at Bath on Friday, July 17th. The statutory Annual General Meeting will be held on the afternoon of Tuesday, July 21st, in the Concert Hall, and on the evening of the same day the new President will deliver his Address to the Association in the Palace Theatre. The twelve Sections among which the scientific and clinical work of the meeting is being divided this year, will meet on the three following days, July 22nd, 23rd, and 24th. The list of Sections and sectional officers, together with the full provisional programme and time table and announcements about hotel accommodation, etc., are published in the SUPPLEMENT to the BRITISH MEDICAL JOURNAL this week. On the last day of the meeting, Saturday, July 25th, there will be excursions to places of interest in the neighbouring West Country. We publish

below the fourth of a series of descriptive and historical articles on Bath. The British Medical Association last met in that city in 1878.

## BATH AND THE POETS.

BY

JOHN HATTON,

DIRECTOR OF THE ROYAL MINERAL BATHS

BATH certainly has done its share in inspiring the poetic muse. Whether it is the effect of its waters, or the stately grace of its architecture, or the beauty of its situation, or whether it is that literary interests are here rather more strongly developed than is usual and the stirring of wit on it produces almost a shower of divine sparks, might form a pretty subject for debate. Whatever the cause, this much is certain, poets do write about it. About Bath itself, its springs, its buildings, its beauties, natural and artificial. And the men and women of Bath who live only through their creators' pens, but more vividly to many than those of flesh and blood—what a fascinating and very human company they form. Across the pages of the last five hundred years or more they make a goodly procession, these literary characters of Bath. Chaucer is responsible for their leader

A good wife was there of beside Bath  
But she was some deal dwe, and that was scath  
Of cloth making she had such an haunt  
She passed them of Ypres and of Gaunt

Next comes Shakespeare

Cupid lud by his brand and fell asleep  
A maid of Druis thus advent'ge found  
And his love finding fire did quickly steep  
In a cold valley fountain of that ground  
Which borrow'd from his holy fire of love  
A dateless lively heat still to endure  
And give a seething bath which yet me prove  
Against strange maladies a sovereign cure

It is not only the poets who have been inspired by Bath, the novelists and the dramatists demand a place in the procession. Here, headed by the Strip-violeted Rodenel Pandom, is the queer collection gathered together by Dr Tobias Smollett in the intervals of failing to build up a plot and quarrelling with his professional brethren.

Once everybody knew them, now they are but almost forgotten names, and so they pass disconsolate—Miss Snapper and Miss Snapper, and Narcissa. Mr Freeman and Godfrey Gruntlett. A faint "Hallo!" comes from the fox-hunting Squire, and Peregrine Pickle can still find a few nodding acquaintances. Then, strangely incongruous in such surroundings, and like a faint ghost, for he does not really belong here and is only allowed in our procession because his

spirit was evoked in Bath, comes Robinson Crusoe, for here it is said Defoe met Alexander Selkirk and heard from his lips the story which later he gave to the world as the history of Robinson Crusoe.

Tom Jones and Squire Allworthy are far from shadowy, for both have good Somerset blood in their veins, even if the real Squire Allworthy—for he is almost a portrait—was that great Cornishman, Ralph Allen, who became the Man of Bath. Fielding is naturally well represented, for he lived on the edges of Bath, in Twerton and Widcombe, and was a welcome guest at Prior Park, and so Squire Western comes blustering along, and Tom nearly loses Sophia, and Miss Bridget Allworthy and the Blifils complete a group typical of the West Country when George the Second reigned.

There was a breath of the fresh air of the downs in Fielding's men, and something of the West Country apple blossom in his women, but the artificiality of the town is thick on Christopher Anstey's sprightly, amusing, objectionable B---n---r---d Family. Mr Simpkin B---n---r---d, Miss Prudence B---n---r---d, Miss Jennet W---d---n and Tabitha Ruit, in spite of their long journey, find Bath to their liking.

Two hundred and sixty long miles are we come  
Tis a plaguy long way—but I ne'er can repine,  
As my stomach is weak, and my spirits decline  
For the people say here—be whatever your ease,  
You are sure to get well if you come to this place

for after recovering from their journey and the "Charming sweet sounds both of fiddles and bells," which welcomed their arrival, they soon find that

Of all the gay places the world can afford,  
By gentle and simple for pastime adored  
Fine balls, and fine concerts, fine buildings, and springs,  
Fine walks and fine views and a thousand fine things,  
(Not to mention the sweet situation and air)  
What place my dear mother with Bath can compare?

There seems no keeping *The New Bath Guide* out of anything about Bath, and even if we nowadays can scarcely agree with Horace Walpole that "so much humour, fun and poetry, so much originality, never met together before," this witty, slightly indecent book probably gives the truest

picture we have of, at any rate, a large section of Bath society in the eighteenth century.

Now comes a familiar group, benighted and feathered, powdered and perfumed. Sir Anthony Absolute drinking protestingly his glass of water and bullying his son between each dose, Sir Lucius O'Tigger telling Bob Acres of the very snug lying in the Abbey, Lydia, languishing exquisitely, and Julia distracted by her Fankland, Mr Fag (of Bath), David (of the county), and the useful Lucy, and Miss Malaprop herself, destined to bring Mr Sheridan a more lasting fame than all his eloquence and statesmanship.

Fanny Burney has passed quickly with all the people from  *Evelina*, and then there is another faint whiff of bygone perfume—lavender, surely, this time, clean and with just a tinge of pungency—and Catherine Morland appears, with Henry Tilney, and the General. Bath gave Jane Austen many of her characters, and with her one may still sit in the Pump Room and see the perennial comedy played again and again—the same play, but brought up to date and redressed, as the producers say. Miss Thorpe and Isabella and John Thorpe are there, and Miss and Mr Allen, and James Morland and Miss Tilney are not far to seek.

Next we hear the voice of Cyrus Angelo Bantam, Esquire, Master of the Ceremonies.

"Welcome to Bath sir. This is indeed an acquisition. Most welcome to Bath sir. It is long, very long Mr Pickwick, since you drank the waters. It appears an age, Mr Pickwick. Re-markable!"

This leads in Mr Pickwick himself, the devoted Sam Weller, and those sticklers for the rigour of the game, the Dowager Lady Snaphrugh and Miss Colonel Wugsby. (Miss Bolo has already gone home in a flood of tears and a sedan chair) and Mr Winkle, still suffering some embarrassment from his endeavours to be helpful, and a little group of footmen and fat chairmen and thin chairmen who hurry up to take their places in the procession, wiping from their lips the remains of boiled mutton with the usual trimmings.

More and more figures pass. There is Monsieur Beaucaire and the Incomparable Bellairs, but many are shadowy and have fading names. Victorians and Edwardians and an ever-growing group, the creatures of this present age. So we leave them, with Mr H G Wells's Sir Richmond Hardy and Miss Grammont.

"They went to the parapet above the river and stood there, leaning over it elbow to elbow and smoking cigarettes. Away in some sunken gardens ahead of them a band was playing and a cluster of little lights about the bandstand showed a crowd of people down below dancing on the grass. These little lights, these bobbing black heads and the lilting music this little inflamed centre of throbbing sounds and ruddy illumination made the dome of the moonlit world about it seem very vast and cool and silent. Our visitors began to realize that Bath could be very beautiful—there was Pulteney Bridge with its noble arch its effect of height over the swelling river and the cluster of houses above more beautiful than the Ponte Vecchio at Florence. It is the most beautiful bridge in the world," said Miss Grammont.

The members of the British Medical Association may perhaps have some means of rendering themselves immune to the attacks of *B. pocticus*, *B. bathoniensis*, or the close of the Annual Meeting may see a serious outbreak of such Friewell Odes as Lady Mary Wortley Montagu's beginning "To all you ladies now at Bath." And if a few moments have been snatched from Sectional Meetings and other important matters, to view Bath from Beechen

Chiff and see the grey city in its green cup, someone may say with the eighteenth century John Scott

Bath ere I quit thy pleasing scene  
Thy beechen cliff I'll climb again  
To view thy mountains' vivid green,  
To view th' hill surrounded plain  
To see distinct beneath the eve  
As in a pictured prospect nigh  
Those attic structures shining white  
That form th' sunny crescent's bend

Or it may be after nightfall, when the velvet valley is pink with a thousand points of light, and the city is, as Henry Chappell, the porter poet of Bath, says

Bathed in ghostly light  
Asleep at peace beneath the witching beam,  
Seeming within the soft embrace of Night  
To be the beautiful City of a dream

A great poet can praise greatly, and few finer tributes have been paid to any city than Swinburne's *Ballad of Bath*—too long to quote in full here, and too beautiful to quote in clipped extract.

Many writers have found Bath a congenial place of residence. Frederic Harrison spent the last years of his long life here, Mrs C N Williamson, who has ranged over most of the countries of Europe "Rita," who found in Bath both the characters and setting for one of her most popular works, and that distinguished authority on literature and wines, Professor George Santsbury.

Bath has a famous writer this year is Mayoresse, Madame Sarah Grand, who will assist in welcoming the members of the Association to the city she loves and has made her home.

"I happened upon Bath accidentally" (Madame Sarah Grand has written). "One day the question was, 'Where shall we go for a change?' And one said 'Let's go to Bath the Beautiful.' So we went for a month and at the end of the month we were singing a chorus song of praise like the Lotus Eaters and one said, 'Let's stay for ever in Bath the Beloved.'"

So we stayed, where history, archaeology, and the picturesque jostle each other at every turn where poetry and romance are in the air, and character walks the streets where music holds its own and philanthropy has more than enough to do where the invalid throws away his sticks or forsakes his bathchair in a week, where the provision shops overflow with good things for the gourmet and he may have green peas and new potatoes out of his garden till the end of November. And as to society—surely there never was a more sociable, more hospitable, friendlier place or pleasanter people, or more liberal minded. It is not so Bath and die, but see Bath and live, and let live. Differences of opinion all go into the social stockpot here and reappear as food for conversation. Bitterness dies in Bath of the prevalent sense of humour and love of fun.

### SICKNESS INSURANCE FOR MEDICAL MEN

The risk every medical man runs to a greater or less extent of being stopped in his work by disablement through illness or accident is now realized by most members of the profession. The work of the majority is so personal in its nature that if a man is prevented from attending to it himself he must suffer serious pecuniary loss, both direct and indirect. Physicians, surgeons, and specialists have to depend entirely upon their ability to give constant personal attention to their patients, and the same is true of general practitioners, though perhaps to a lessened extent when they are in partnership. Those who are engaged in the public health service, or who hold institutional appointments, are not exposed to quite the same immediate risks, as frequently the contract of service

The Royal Roman Bath and Cross Bath with Royal United Hospital in the background (From a wood engraving by Horace Gerrard)

they hold with a local authority is adequate to help them through a temporary period of illness or disablement, but if the period becomes prolonged they also are exposed to serious losses. It is therefore incumbent on every medical man engaged in practice to build up for himself a strong reserve fund which can be drawn upon to meet the expenses incurred through disability from accident or illness. Probably the surest and safest way of providing for such contingencies is by an insurance contract. Recent experience has shown, what indeed ought to have been obvious, that the terms of the contract must be very carefully examined and that it should not be concluded without obtaining skilled advice.

An interesting example of how men have helped themselves is provided in the development of what is known as the Holloway group of friendly societies. Members of friendly societies enjoy certain privileges, but have to submit to certain restrictions, which tend to impair a society's usefulness to members of the medical profession. There have also been tried during the last fifty years various methods of protection by insurance companies who have sought to meet the requirements of the medical and other professions. The forms of protection offered by the insurance companies have followed two main lines.

1. An annual contract—that is, a policy providing for a fixed payment in the event of disablement from sickness or accident during a period usually not exceeding twenty-six weeks, together with capital sums payable in the event of death or loss of limbs or eyes. As a rule these contracts can be obtained without any medical examination, and it is possible for either party to terminate the contract at the end of the policy year. These contracts are obtainable at a comparatively low premium but they are of less value to the medical man who desires protection over a long period than to commercial classes with less need for sickness insurance.

2. The non-cancellable contract—that is to say, a policy which providing its conditions are complied with can be continued in force until an agreed age, but not beyond age 65.

The companies granting these contracts have no power to vary the conditions of the policy or exclude any diseases no matter how frequent or prolonged the disablements may be. The permanency of these contracts gives them an increasing value, and they have been very largely taken up by all sections of the medical profession. The policies for which there is the largest demand provide for payment in the event of disablement in one of two well established ways.

The first is by a contract for immediate payment for any disability which lasts more than seven days; the payment continues in full for twenty-six weeks but is then reduced by one-half for the remainder of the disablement up to the termination of the agreed period.

The other is the deferred non-reducible system. Under it there is no payment for the first four weeks, three months, or six months of any disablement, as may be preferred, but the full amount is paid thereafter so long as the disablement lasts up to the agreed age.

Quite recently a new form of policy has been granted, which provides for immediate and non-reducible payments. Whilst attractive this form of contract is unsound in theory. In the first place the statistics upon which the premiums have been calculated do not extend to show a non-reducible benefit, and the companies offering this form of contract are therefore experimenting with this class of insurance. In the second place, such a contract removes the principal inducement to an early recovery from disability, which is undesirable both from the point of view of the company and the assured.

Yet another experiment is being made which has appealed particularly to some members of the medical profession, and should receive careful consideration. It is a practice of the friendly societies to make payment to its members who are totally unable to follow the occupation in which they have been engaged. Some insurance companies have granted contracts of a similar nature to surgeons and general practitioners. It would appear that if it is

possible for a friendly society to grant this form of protection then there ought to be no reason why an insurance company should not do it, but it must be borne in mind that while a friendly society has the privilege of altering its conditions by a vote of its members, there is no such freedom reserved by an insurance company. Once an insurance company has granted its contract it is bound by its conditions. It may sound very attractive to a surgeon to be able to get a sickness and accident policy which purports to issue a definite weekly payment if he is unable to follow the specific side of the profession that he is practising, but it must be recognized that the premiums that are charged for sickness and accident insurance are not calculated to provide for any such risk, and, while it may appear a very desirable contract, it may really be that the company is undertaking liabilities for which no adequate provision is being made. This point is of such importance that it needs to be carefully examined. For instance, supposing a surgeon seriously injured his right hand, it might prevent him from following his ordinary professional duties, and be sufficient to enable him to establish a claim within the meaning of the policy, but when the injury had healed, although he might still be unable to operate, the condition of his general health might not be in any way impaired, and he would be able to devote his knowledge and attention to another part of the profession. He might be unable to earn so large an income as when doing his special work, but he might be able to make good in another direction. An insurance company granting such a policy might have to pay an annuity up to the agreed age, although the policy holder was in a position to make an income in another branch of the profession, and was actually doing so. Some of the insurance companies that have had considerable experience in sickness and accident insurance decline to grant such contracts.

Another effect of this condition providing for total incapacity to follow a specific line of practice is to make possible claims for partial disablement. An experienced actuary has given the following opinion upon this aspect of the subject:

"The sickness portion of a permanent sickness and accident policy only covers total disablement. It is always possible for an additional premium to protect oneself against partial disablement by accident for a sum assured, which is usually one-fourth or at the most one-third of the sum assured payable in event of total disablement but it is not possible to effect an insurance against partial disablement by sickness. It would probably be regarded as rashness in this age of enterprise to predict that any particular condition would never lend itself to insurance treatment but if an exception to an otherwise wholesome rule, viz., not to prophesy before you know, could be made, I should venture to claim that this exception must be that of providing partial disablement benefit under a sickness policy. It is a multifarious condition capable neither of precise statement nor of treatment from the insurance standpoint. The system can only be framed upon general lines and it can only provide therefore for total disablement."

The position with regard to sickness and accident insurance has now reached a stage which calls for the most serious consideration of the profession. The companies that have the longest experience have been operating for about forty years, but they will probably require carefully to observe their experience for another fifteen years in order to obtain trustworthy vital statistics. The selection of risks requires special skill, and the incidence of certain diseases demands constant observation. A conservative attitude towards this special class of insurance is therefore to the advantage of both the general public and the companies.

The oldest companies enjoy large reserve funds, which are periodically valued on a stringent actuarial basis. In life assurance it is always possible to know the basis of the valuation that the company uses, and the same public should be given to sickness and accident funds. There is one office that is always prepared to give this information upon application. In all cases a separate account for sickness and accident funds should be produced. It is hoped that the Board of Trade Committee which is considering the Assurance Companies Act, 1909, will make it compulsory upon all companies transacting permanent sickness business to make returns to the Board of Trade.

in the same manner as life companies do at the present time

It is desirable that a medical man, before entering into any contract for sickness and accident insurance, should avail himself of the guidance that is obtainable from the Medical Insurance Agency (British Medical Association House, Tavistock Square, London, W.C.1)

It cannot be too often emphasized that, just as a medical man who intends investing funds seeks either the counsel of his bank manager or stockbroker, from whom he expects an independent opinion, so he should seek in like manner the aid of the Medical Insurance Agency, which exists to give him free, independent, and impartial advice upon all insurance matters

## INTERNATIONAL CONGRESS OF RADIOLOGY

### FIRST DAY'S PROCEEDINGS

THE International Congress of Radiology began its heavy programme of work on July 1st at the Central Hall, Westminster, under the general presidency of Mr C THURSTON HOLLAND of Liverpool. The members attending, exceed by at least one hundred the anticipations of the organizers. Up to the eve of the Congress close upon 500 members had registered, more than half of whom came from abroad. In the first list of 350 arrivals, 60 were from Germany, 30 from France and Belgium, 12 from Italy, and just over 50 from the United States. Constantinople and Buenos Aires and Moscow were all represented, and a contingent came from the State Institute of Roentgenology, Leningrad.

On the evening before the Congress a reception, which was very largely attended, was given by the executive of the Congress at the house of the Royal Society of Medicine. Members and their friends were received by Mr Thurston Holland. An exhibition of old books, prints, and curiosities in the possession of the Royal Society of Medicine had been arranged, there was a cinematograph display, and Dr Murray Levick gave a lecture, illustrated by his own photographs, on the habits of the Adello penguins in the Antarctic.

#### OFFICIAL OPENING CEREMONY

H.R.H. the DUKE OF CONNAUGHT opened the Congress officially on Wednesday afternoon, July 1st. Among those on the platform, besides the President and officers of the Congress, were Mr Neville Chamberlain (Minister of Health), Lord Dawson of Penn, Sir Humphry Rolleston, and Sir George Newman. Delegates were introduced representing the radiological societies of the Dominions and of various foreign countries.

The Duke of Connaught said that it was an eloquent tribute to the value of Roentgen's discovery that, thirty years afterwards, such a large body of scientists and medical men should meet to discuss the many directions in which the science had developed. The dreams of the earlier days might not have been all fulfilled, but there were reasons for believing that with the more intelligent appreciation of the effects of x-rays more striking advances might be made. The consuming question that interested scientists and medical men the world over was the discovery of the cause and treatment of cancer. No surer method of promoting cordial international relations could be imagined than the meeting in congress of the leading intellects of all countries. His Royal Highness went on to speak of the value of mobile x-ray outfits which could be taken to the patient's bedside, of the work of the British Institute of Radiology, and of the research on radium which was proceeding in this and other countries.

Mr NEVILLE CHAMBERLAIN welcomed the members on behalf of the Government. He said that few could have anticipated in the early days of Roentgen's discovery what it meant for mankind. Such succeeding discoveries in this province seemed only to lift the curtain a little higher, and to indicate still further possibilities opening out. He did not believe that advances could be made except by continual research and experiment, to the interplay of

minds devoted to these problems. It was the duty of his department to do all that it could to encourage research. At present this was hampered, so far as radium was concerned, by the fact that radium was both scarce and dear. Mr Chamberlain went on to say that the path of exploration was always strewn with wreckage, and very often with the bones of explorers, and radiology had been no exception. Not a few of the pioneers had fallen victims to dangers which at the beginning were unrecognized. All honour to such pioneers! They had moved the rocks for others. He did not doubt that when the Congress closed all its members would feel that another step had been taken towards further triumphs for the benefit of humanity.

Sir HUMPHRY ROLLESTON conveyed the thanks of the Congress to His Royal Highness, and went on to speak of the British Institute of Radiology and the hopes and ambitions it represented. He could not help feeling that the Congress and the Institute were very closely related. The Congress was in the butterfly stage, and worked intensively for a short time, but the Institute was in the larval stage and carried on its work from day to day. The Institute deserved all possible encouragement and help, for it was a sort of central bureau where all matters connected with radiology could be stored, discussed, and provided to any radiologist or other medical man requiring them. The Institute would become the centre of a worldwide organization for systematic research.

#### INTERNATIONAL UNITS AND STANDARDS FOR X-RAY WORK

A joint meeting of the Sections of Physics and Radiology was held on Wednesday morning to discuss the subject of international units and standards for x-ray work.

Sir WILLIAM BRUCE, in a brief introduction, referred to the difficulties surrounding the problem, which he said, must be settled on the basis of compromise. There were three factors which must be isolated: (1) the determination of a scientific unit, which was a matter of physics pure and simple, (2) the determination of a standard or description of an apparatus which could be used for comparison, (3) the comparison of this standard with the results obtained in treatment. It was of no use arriving at any one of these factors to an extreme conclusion and leaving the others indefinite, because, just as the strongest part of a chain was its weakest link, so any indefiniteness in any one of these divisions would govern the value of the work in others.

Dr H. BLEIBERG, speaking in French, said that radiologists must look to radium to supply the physical unit of dosage for fundamental standardization. He called upon radiologists of all countries to attempt a standardization of dosage which might be common to them all, and to elect an international committee for the study of this very important question, such committee to be composed of medical men and physicists.

Dr N. S. FINZI (London) seconded this proposal. The most difficult question, in his view, would be the setting up of a biological unit on account of the numerous factors, such as wave lengths of radiation employed and duration, which had to be reckoned with. If radium were used in standardization, the beta radiation should be eliminated.

Others who joined in the discussion were Dr W. ALTSCHUL (Pisa), Dr I. SER SOLOMON (Paris), Dr J. H. SHAW (Cardiff), and Dr H. MOORE (London). The last-named expressed the opinion that the most important step was to provide radiologists with a generating apparatus with which they could get an x-ray beam of definite quality. Given this factor, the problem of dosage would solve itself. The solution was in the hands of radiologists if they chose to scrap their present apparatus and to install a constant voltage apparatus, the only deterrent was cost.

A motion to elect an international committee for the study of this question was carried.

#### Periodical International Congresses

The international delegates conferred during the meeting, and it was agreed that the Congress should be constituted the first International Congress of Radiology, which means that it is to be followed by others in different countries.

## Victoria.

[FROM OUR SPECIAL CORRESPONDENT]

### NEW HOUSE OF THE VICTORIAN BRANCH

THE Victorian Branch of the British Medical Association decided a short time ago to build itself a new house. It has recently been completed and was formally opened on May 20th. It is of concrete, in three stories, and has cost £11,000. In the entrance hall a memorial has been erected to members who fell in the great war, on the same floor is a meeting hall capable of seating 350 people. On the first floor is a library, a reading room, the council chamber, and offices.

At the opening ceremony the chair was taken by Dr Argyle, President of the Branch, who was accompanied on the platform by the Attorney-General of Victoria, the Lord Mayor of Melbourne, the two vice-presidents of the Branch, the vice-president of the New South Wales Branch, the Dean of the Faculty of Medicine, Melbourne University, the chairmen of committees, the honorary secretary, and the chairman of the Building Committee. Dr R. H. Fotherston, convenor of the Building Committee, gave a brief history of the old hall and the circumstances which led to the erection of the new building.

#### President's Address

The President (Dr Argyle) then gave an address. In 1879 the Victorian Branch, he said, was founded with 62 members, to-day it had 1,185. He then sketched the development of modern knowledge since the Branch was founded, referring in particular to the establishment of antiseptic surgery by Lister. The system came into use in the Melbourne Hospital in the early eighties, and by a process akin to revolution it had now been replaced by aseptic methods, the use of which rendered it possible for a surgeon to operate on every region of the body with practically no risk at all from the operation. He then touched upon some of the developments of bacteriology which had enabled preventive medicine to become a real force in the community. Typhoid fever had practically vanished in large cities. In Victoria in 1878 the deaths from that fever were 50.7 per 100,000, to-day the rate was only 2 per 100,000. With adequate sewerage in the country towns the disease would vanish altogether. Deaths from diphtheria in Victoria in 1878 were 65.4 per 100,000, to-day the rate had dropped to 7 per 100,000. Tuberculosis in 1878 claimed 1,678 per 100,000, to-day only 71.1. Within the same period physiology and pathology, assisted by biochemistry and physical science, had moved forward in no uncertain way, investigators were busy in the diagnostic field, and in epidemic and tropical diseases the work of biological inquiries had reaped a rich harvest. The greatest contribution to medicine by the physicians was the discovery of the x-rays by Roentgen in 1895. It was almost impossible to overestimate the value of the method in both medicine and surgery. No hospital was complete, no textbook up to date, no practitioner safe, if the x-rays were not regularly used as part of the daily routine for the accurate diagnosis of injury or disease. The discovery of radium by M. and Madame Curie in 1898 added yet another physical weapon for the treatment of cancer and allied conditions. Many puzzling diseases of nutrition were now known to be deficiency diseases due to the lack of some element in the food supply. But though much had been done there remained much to do, especially in regard to tuberculosis and cancer. The net result of all the discoveries and activities during the last forty-seven years was remarkable. In Victoria in 1878 the death rate per 1,000 was 14.56, in 1924 it was 10.05. The medical profession in Victoria had done its part in the great war of 956 members, 407 enlisted for active service (about 42 per cent), and of these 43 (10.5 per cent) died on service. One-third of those who remained behind also did war service.

In declaring the building open Dr Argyle used the words of Dr Osborn Taylor to dedicate it: "To the noble profession, whose gospel is the healing of mankind, whose honour is the Hippocratic oath."

The Attorney General (Mr Eggleston), after congratulating the Branch on its acquisition of such a fine home, said that the general community did not fully realize the extent of its indebtedness to the medical profession, or the magnitude of the sacrifices which members of the profession frequently made.

The Lord Mayor of Melbourne expressed the congratulations of the citizens, and Dr C. G. Laws spoke in the name of the New South Wales Branch, of which he is vice-president. Dr Douglas Stephens, senior vice-president of the Victorian Branch, also responded, and Dr J. Newman Morris, on behalf of the members of the Branch, presented Dr Fotherston with a cheque in recognition of his services for the new building. Afterwards a reception was held in the library.

## Scotland.

### MEMORIAL TO SIR WILLIAM MACCOWEN AT ERSKINE

AT the Princess Louisa Scottish Hospital for Limbless Sailors and Soldiers at Eiskine there was unveiled on June 20th a memorial to the late Sir William Maccowen. As one of the pioneers in the founding of this hospital, Sir William devoted himself with great energy and enthusiasm to the work carried on there during the war, and it was largely to his splendid services and surgical skill that the institution owed its success. The memorial takes the form of a mural tablet, designed by Mr G. H. Paulin, and is placed in the entrance hall of the main building, and upon it due recognition is made, not only of his association with Eiskine, but also of his outstanding achievements and world-wide fame in the realm of surgery. The tablet is of bronze set in marble, and bears the following inscription:

"In honour of Sir William Maccowen C.B. D.L. F.R.S., Honorary Surgeon to the King in Scotland, Regius Professor of Surgery in the University of Glasgow, a world-renowned surgeon, a great man to whom this hospital owes its inception to whose untiring labours its success is due. Who within these walls, by his skill restored to active and useful lives many of those maimed and broken in the Great War."

Over the tablet was placed a wreath designed by H. R. H. Princess Louise, who had hoped to attend the ceremony, but whose health did not permit of the journey north. In her absence the unveiling was performed by Principal Sir Donald MacAlister, Bt., who delivered a graceful and eloquent oration on Sir William Maccowen and his services to the hospital, in the presence of a large company. Sir John Reid, in handing over the memorial to the custody of the Lord Provost of Glasgow on behalf of the hospital, read a personal letter which he recently received from Princess Louise, in which Her Royal Highness expressed her great regret that she could not attend and take part in the proceedings. "It is a very real disappointment to me," she added, "to have to write this to you, as I have been counting all along on coming to be among you all, who have so kindly wished me to be with you for this occasion at Eiskine House, which I am proud of looking upon as my hospital, for, as you well know, I take a true and affectionate interest in it. It was Sir William's special child, which he created and put his whole heart and soul into." Sir John Reid joined in paying tribute to the work of Sir William, as did also Lord Provost M. W. Montgomery in accepting custody of the memorial. Dr James A. Adams spoke in the name of the medical profession. Dr J. A. C. Maccowen, speaking on behalf of Lady Maccowen and his sisters and brothers, expressed appreciation of the graceful tribute that had been rendered to his father's memoir. In proposing a vote of thanks to the Lord Provost, the Marchioness of Ailsa said the tablet spoke with admiration and gratitude of Sir William's services to the hospital, but the real memorial would be the carrying to completion of the ideal he so magnificently conceived of establishing it as a permanent national institution for the benefit of disabled sailors and soldiers.

## WILLIAM AND JOHN HUNTER MEMORIAL AT GLASGOW

The University of Glasgow on June 24th conferred honorary degrees on a number of distinguished men, and afterwards another ceremony took place at which homage was paid to the memory of two great medical brothers, William and John Hunter, who were natives of East Kilbride, the former a student and graduate of Glasgow University. Both proceeded to London, where they achieved great distinction, one as a physician and the other as a surgeon. In common they were creators of great and invaluable museums. William gave to Glasgow University the Hunterian Museum, remarkable not only for collections in anatomy, natural history, and a fine library of books and manuscripts, but also for a world renowned collection of coins. John Hunter, "the pioneer of all that is philosophic in modern biology," presented his museum to the Royal College of Surgeons of England. The memorial to the brothers has been erected in the University grounds on a lawn facing University Avenue, and forms a striking piece of architecture. Built of white stone, it is enclosed in a three-sided rectangular stone court formed by low walls having stone ledge seats, and is approached by a short flight of steps. Rising from its rear wall is the main feature of the monument—a squat stone with two shoulders of panelled wall. On the upper part of the centre stone are the arms of Glasgow University, below which is the following inscription:

"In gratiam memoriam fratrum de scientia naturali et medendi arte Optime meritorum Gulielmi (1718-1783) et Johannis Hunter (1728-1793) quorum uterque famae venitor aeternae hic collegium chirurgicum Londini regum ille Glasguae alumnus idem et dator matrem studiorum Universitatem musaeo condito ornavit

On either side of the main piece are chiselled heads of the two brothers, while on the east and west ends respectively of the higher walls are the arms of the Royal College of Surgeons of England and the Royal Faculty of Physicians and Surgeons of Glasgow. The origin of the memorial dates back to 1893, when the idea was first mooted by the late Dr. George Ritchie Mathew when publishing a biography of the two brothers. Unfortunately, before any steps could be taken in furthering the idea Dr. Mathew died, but his suggestion lived, and has now matured in the present memorial. Mrs. Mathew, his widow, who strongly supported the proposal and has been instrumental in having his wishes carried out, had the privilege, as was most fitting, of unveiling the monument. On behalf of the subscribers Dr. David Murray, chairman of the Memorial Committee, formally asked the University authorities to accept custody of the memorial, "to commemorate two Lanarkshire men who by their own genius, without the aid of powerful friends or by the chances of fortune, attained to the highest eminence, and from whose careers we should learn that whatever is to be of enduring value must be the outcome of individual effort, of self-reliance, and of unremitting labour." Sir Donald MacAlister gratefully accepted custody of the memorial in the name and by the authority of the University Court. In so doing he said that the University, though its field of service was wider than the city, the west country, or the Scottish homeland itself, had yet a special relation and responsibility to these. It had to keep before the eyes of the citizens of Glasgow, and of actual and potential students who frequented its precincts, visible tokens of the things it stood for and sought to foster. Its buildings should be stately and suggest the dignity of learning. Its grounds for health, exercise and recreation should be ample and seemly, and so manifest the fostering care of Alma Mater for the well-being of her alumni. Its public museums should be comprehensive and well furnished, that minus the most various might find therein matter to stimulate interest and evoke intelligent inquiry. Its portraits and memorials of the worthies who were exercised within its walls should be many and conspicuous, that examples of excellence in their several kinds might be held up before all, and set forth visibly as the abiding heritage of their successors for encouragement and imitation. This memorial to the brothers Hunter enriched the University in more than one of these respects. It told in especial of two humble Glasgow students who by dint of

industry and native talent, rose to fame as leaders of science and benefactors of their kind. It said with silent eloquence, "What Glasgow students did, Glasgow students can do." For this additional stimulus to higher endeavour the students and teachers of the University thankfully acknowledged their debt to the contributors. Sir John Blund Sutton, Bt., President of the Royal College of Surgeons of England, who at the graduation was the recipient of the degree of LL.D., spoke as representing John Hunter, and Professor F. K. Monro, President of the Royal Faculty of Physicians and Surgeons of Glasgow, as representing William Hunter. In doing so both paid tribute to the memory of these great medical brothers, who each in his own way had won fame, and whose names are still held in reverence.

## EFFECTS OF THYROID EXTRACT ON ACID FOWLS

At a meeting of the Royal Society of Edinburgh on June 22nd, when Principal Sir Alfred Irving was in the chair, a paper was contributed by Dr. I. A. L. Crow, director of the Animal Breeding Research Department of Edinburgh University, on rejuvenation of the aged fowl through thyroid medication. Dr. Crow said that as a fowl got old its plumage got lighter and its fecundity decreased. Experiments had shown that the cause of this was, possibly, a progressive inefficient functioning of the thyroid gland. Desiccated thyroid had been given to old fowls, with the result that all the birds became rejuvenated, the plumage of the cocks becoming similar to that of normal hens, whilst the egg yield of the hens was increased to a remarkable extent.

## GRANT TO ROYAL SIMPSON MEMORIAL HOSPITAL

On June 24th a deputation from the Royal Maternity and Simpson Memorial Hospital, Edinburgh, met the Lord Provost's Committee of Edinburgh Town Council to support an application for a grant towards capital expenditure. The deputation explained that property in the neighbourhood of the hospital had recently been purchased at a price of £650, and that the cost of alterations necessary to adapt this property for the purposes of the hospital would be about £950. The Lord Provost's Committee agreed to recommend that the town council should grant £950 to the hospital for this purpose.

## CENTRAL MIDWIVES BOARD FOR SCOTLAND

At a meeting of the Central Midwives Board for Scotland on June 24th Dr. James Haig Ferguson was in the chair, and Sir Archibald Buchan-Hepburn, Bt., was appointed deputy chairman in place of the late Dr. Michael Dewar. Intimation was made that the Scottish Board of Health had approved the new rules for extended training of midwifery nurses, which come into force on May 1st, 1926, and will apply to all persons commencing midwifery training thereafter.

## Ireland.

IRISH FREE STATE PENSION RIGHTS  
Important Notification

Medical officials under county health boards and other local authorities should bear in mind that if they desire to avail themselves, for pension purposes, of Section 8 of the Local Government Act, 1919, they must notify their local authorities of their intention at a date not later than July 25th next. The following summary of the pension rights of medical officers under the Acts of 1919 and 1925 has been addressed to Local Medical Committees by the Irish Medical Society. What the medical officers affected have to consider is whether in each individual case the benefits of Section 8 of the Act of 1919, and in certain cases the benefits of the Local Government, 1898 Act, gave more favourable terms than the benefits under the Act of 1925. (1) Generally, the older provisions appear more favourable, but we prefer not to lay down any hard and fast rule, as there may be some cases in which the terms of the more recent Act would operate to greater

advantage than those of the earlier Acts. We desire to call particular attention to the fact that there is no scale save a maximum one prescribed by the 1925 Act. Subject to this the Minister has arbitrary power. (2) Under Section 8 of the Local Government Act, 1919, the fact alone that a medical officer is 60 years of age, and has served as an officer of a local authority for not less than twenty years, entitles him, with the consent of the Minister, (i) to resign his office, and (ii) to receive a mandatory pension on a defined minimal and maximal scale. No medical certificate of permanent disability is required with these conditions. Under the Local Government Act, 1925, a medical officer to resign under the conditions (just mentioned) of the Local Government Act, 1919, must have attained 65 years of age and must have twenty-five years' service—that is, under the 1925 Act, an extra five years is added to each condition. The recent Act (1925) would be more advantageous (a) in the case of women doctors who, on marriage, would resign their offices, (b) in some respects in the case of a medical officer who had served in a pensionable office outside the area of his present pensioning authority—that is, the County Health Board. The following draft letter might be employed by medical officers who prefer to retain their rights under the Act of 1919.

Address and Date  
Board of Health

To the Secretary

Sir,  
I beg to notify you for the information of Board of Health that it is not my intention to avail myself of the provisions of Part 4 of the Local Government Act 1925 with the exception of the several sections which by Section 43 of that Act are made applicable to an officer making the election which I am doing.

I am Yours faithfully

## England and Wales.

### THE LONDON UNIVERSITY SITE

THE correspondence between the Principal Officer of the University of London and the Treasury, which is printed at page 43, would, if taken literally on its face value, appear to amount to a final decision that the University headquarters shall not be established in the Bloomsbury district, as was proposed some time ago, when the Government, through the mouth of Mr H A L Fisher, then President of the Board of Education, made a definite offer of a site, subject to certain contingencies set out in the correspondence. Lord Haldane, when opening the new headquarters of the National Union of Students of the Universities and University Colleges of England and Wales, in Endsleigh Street, Bloomsbury, last week, said that the Royal Commission on University Education in London, of which he was chairman, had, among other things, reported that London must have a university centre, and that the centre should be Bloomsbury. There was no situation in London comparable to that neighbourhood for the home of the University, for headquarters, for lecture rooms, or for a club house and an assembly place for students. The University would not achieve success unless it avoided the extreme act of folly which it seemed about to commit in not setting to work to get a constitution for the University. The Union he was addressing was formed three years ago, and already includes about 30,000 undergraduates. The new building provides an adequate central office and club rooms. A university, Lord Haldane said, was essentially dependent on its atmosphere. In the Union there was a body of students, women as well as men, who represented the university atmosphere from different parts of the world. University students, men and women, wherever they might be, whether in Washington, Tokyo, Berlin, or Paris, thought alike, provided only there was a sufficient height of knowledge. London, the greatest city in point of numbers in the world, and not diminishing in importance, was without a proper university. There were in London many colleges, several of which exceeded

in size universities in the provinces, but they were not brought together under one roof, and it was not easy to bring them under one roof. He himself had been at work on the problem for over thirty years.

### GUY'S HOSPITAL MEDICAL SCHOOL

The annual Guy's Hospital garden party—a pleasant event in pre-war days—was revived on June 29th when H R H the Duke of York, deputizing for the Prince of Wales, who is president of the hospital, distributed the prizes to the successful students in the medical school. The Duke was received by the Treasurer of the hospital (Mr F P Whitbread), the Vice-Chancellor of the University of London (Professor Ernest A Gidner), and the members of the hospital staff, and after a visit to the concert-room for certain presentations, he proceeded to the physiological theatre, where a distinguished company had assembled. The Treasurer extended a hearty welcome to His Royal Highness, and referred to the intimate way in which the progress of the hospital, now in its bicentenary year, had been bound up with the progress of the medical school. The Duke did not address the assembly, but contented himself with distributing the fourteen medical and seven dental prizes and scholarships and individually congratulating the successful students. One remarkable and probably unprecedented success was the winning of the Treasurer's gold medal for clinical medicine and the Treasurer's gold medal for clinical surgery, as well as the Beauchamp prize for pathology, by the same student—Mr D W C Northfield. The brief proceedings concluded with an enthusiastically accorded vote of thanks, moved by Dr Finckh, senior physician to the hospital, who referred to the great traditions of Guy's and the generations of good doctors and wise and humane men who had gone forth from the school. The Duke of York afterwards visited the Henriette Raphael Nurses' Home, where work contributed by the Ladies' Association (of which the Duchess is president) was on view. An interesting collection of antiquities was arranged in one of the departments, it included relics of Thomas Guy and some of the earliest books and prints connected with the hospital. The wards, museum, and laboratories were open to inspection, and each visitor was handed an extremely well got up pamphlet, which contained not only the order of proceedings, but also a history of and guide to the hospital.

### DEPUTATION TO THE MINISTER OF HEALTH FROM THE LONDON COUNTY COUNCIL

A deputation from the London County Council on various matters connected with health administration in London was received by the Minister of Health on June 8th. Mr Neville Chamberlain, in the course of his reply, said that Poor Law reform was part of the programme of the Government for next year, conditional, however, upon the passing during the present session of the Rating and Valuation Bill. One of the questions which would then come up for consideration was the extent to which the present Poor Law infirmaries could be used for the accommodation of advanced cases of tuberculosis, on the surface it seemed as if they would be very suitable, but he thought it was clear that in any satisfactory provision for the institutional treatment of tuberculosis in London there must be some central body capable of taking a survey of the needs of the whole area and seeing that those needs were properly and suitably provided for. This did not necessarily imply with it central administration of the units of institutions—a matter on which he would not like to commit himself at the present time. On another aspect of the tuberculosis problem—that of after-care—the Minister said that he regarded the experiments that had been carried out at Papworth and Preston as extremely interesting and valuable, but they could not provide a complete solution of the problem. There were, however, other experiments in progress or in contemplation for the setting up of workshops in large towns which would be under medical supervision and would work under such conditions as might be laid down by medical advice, but which he did not think could be run without a subvention. He was in communication with the Treasury on the matter, and if he was fortunate enough to soften the heart of the

Chancellor of the Exchequer he might be able to put forward a scheme for grants in aid for certain experimental stations. He also spoke on the subject of refuse disposal and drainage and indicated that he would take steps to secure expert inquiry to see whether certain views put forward by the deputation could be met.

## Correspondence.

### MEDICAL EDUCATION IN WALES

SIR,—As one who has taken a deep interest from its inception in the proposal to establish a really national Welsh School of Medicine, I have read Sir Isambard Owen's letter in your issue of June 20th (p. 1150) with some surprise. I am surprised both by what is said in that letter and by what is omitted from it.

1 Sir Isambard Owen writes "The policy of separating the Cardiff School of Medicine from its parent college was not a recommendation of the recent Royal Commission" that policy, he states, originated with the University and was dictated by financial factors. Sir Isambard Owen omits any mention of the strong move to make a National School of Medicine which developed before the appointment of the Royal Commission. That was, and is, an important factor in the situation, and the final recommendation of the Royal Commission is sufficiently explicit.

216 The endeavour at once to give the School of Medicine a national status and to recognize the special interests of the University College at Cardiff produced a highly complicated plan which was admitted by the Departmental Committee to be only the best that could be devised under disadvantageous conditions. After a careful consideration of the various suggestions in relation to our general task we have decided to recommend the mere simple plan suggested to us by Sir Isambard Owen of organizing the Medical School as a constituent College of the University to be governed under the University by a Council and Senate of its own.

I have italicized the last lines of this quotation because I find it difficult to reconcile them with Sir Isambard Owen's assertion that the policy of separating the Cardiff School of Medicine from its parent college was not a recommendation of the Royal Commission. Any man is as well entitled to change his mind as any woman proverbially is to change hers, but Sir Isambard Owen seems to have executed a complete volte-face.

2 Sir Isambard Owen does not mention that the new scheme of erecting the school as a "school of the university" and not as a "college of the university" was in the first place suggested by the Senate of the College at Cardiff itself. The University Council, in proposing the new scheme of constitution, is in effect bowing to the suggestions of Cardiff College, of the council of which Sir Isambard Owen is a member.

3 Sir Isambard states that the article in the *BRITISH MEDICAL JOURNAL* (which he is criticizing) "seems to suggest that this scheme [that is, the scheme now proposed by the University Council] has the approval of the faculty of medicine of the university, my information is that it has not yet been before the faculty." Sir Isambard Owen is in error when he suggests that the article in the *BRITISH MEDICAL JOURNAL* seems to suggest that the scheme has the approval of the faculty of medicine, although no doubt it would have that approval if submitted to it. The article in the *BRITISH MEDICAL JOURNAL* states quite correctly that the original recommendation of the Royal Commission (in favour of separation as a "college") has been endorsed by the faculty of medicine. It will, perhaps, be a sufficient indication of the way in which the matter is being dealt with by Sir Isambard Owen and his colleagues on the council of Cardiff College if I point out that the college has come to a decision against the scheme, without even taking the opinion thereon of its academic bodies.

4 Another cause of surprise to me is that Sir Isambard Owen, though he refers to the opinion expressed by the Vice-Chancellor of the University of Liverpool in a communication to the *Western Mail*, does not refer to the views previously set out in an article in the same newspaper (February 7th, 1925) by Sir Charles Sherrington, Professor

of Physiology in the University of Oxford, and President of the Royal Society.

Dealing first with the word "separation" as applied to the Medical School, Sir Charles Sherrington said that it might suggest that the school would suffer thereby. It was not, he said, perhaps sufficiently realized that the question of separation will not affect the present academic arrangements, and that those who opposed separation on this ground did so without knowing the true facts of the case. The supreme academic authority of the University is, he pointed out, the Academic Board—composed of representatives of all the faculties of the university. The present academic relationship of the School of Medicine to the University on the one side and to the University College at Cardiff on the other, will remain unaltered in the independent School of Medicine.

He then passed on to consider the question of the independent colleges which would receive from independence. He wrote as follows:

In the first place there will be a more efficient administration of the school, which has to report to (and is subject to) the council of Cardiff College, which again on many matters has to receive the consent of the council of the University. As the Board of Medicine the College Council and the University Council all have their own administrative machinery and sub-committees it is not difficult to see that the present administration of the school is very complicated and slow in action. The proposal to give the School of Medicine independence within the University is essentially a proposal to make its Board of Medicine an effective administrative body with power similar to that of the councils of the constituent colleges of the University. I venture to say that the independence of the school does not entail further academic separation but does involve a more efficient administration of the school.

Under the constitution in favour of which he was writing, the status of the Medical School would, he said, be that of a school of the university carrying on its work in complete harmony with the University College of Cardiff, but functioning as a unit of the university rather than as a department of a constituent college. There was no reason, he believed, why this arrangement of itself should affect academic intercourse, for at Oxford and Cambridge the measure of independence enjoyed by the colleges and the school of medicine did not affect intellectual and take place of how this might be brought about did not depend upon the question of governance. The University of Wales, he continued, occupied a unique position among the universities of Great Britain, not only on account of its federal character, but also because it was a national university in a sense not true of any other British university. It was a single expression of ideals and aspirations of a whole nation, it had several constituent parts, but the university itself was one and undivided. The highest interests of the medical school demanded, in Sir Charles Sherrington's opinion, that it should be associated directly with the national university rather than with one of the constituent parts of that university. This claim was "not only inherent in the federal character of the university, but also records with the importance of medical science as a branch of learning and with its vital bearing upon the well being of the community." The idea of a school of medicine for the whole of the Principality had captured the imagination of the Welsh people, if their hopes were to be realized the young institution must be given full freedom to develop. Complete incorporation of the medical school with the Cardiff College would prevent it from developing on its own lines, would lead to a conflict of interests, and would saddle it with the necessity of submitting to College exigencies. Sir Charles Sherrington concluded his article with the following words:

The nature of the constitution of the University of Wales as well as the national status of the school in my opinion point unmistakably to the recognition of the school as an independent unit of the University. Given the support of the Welsh people and given full freedom of action in framing and directing its own policy it is my hope and expectation that the School of Medicine will go from strength to strength and may come to rank with the finest and most up to date schools in the world.

The real factor in the situation is this that as things

are at present in Cardiff it will not be possible to develop a first-rate school of medicine unless it is separated from the local college and placed directly and fully under the University of Wales itself—I am, etc.,

Leechard, Cardigan hire June 27th JOHN LYNN-THOMAS

### THE DIPLOMAS OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON

SIR,—In your notice of the death of Dr. Edwin John Slade-King, which appeared in the JOURNAL last week (p. 1200), you omitted to mention the fact that Dr. Slade-King was the last medical man left who held the diploma of "Extra Urbem Licentiate" of the Royal College of Physicians. The power to grant the diploma of "Extra Urbem Licentiate" was secured to the College by the statute of 14 and 15 Henry VIII (1522-23), and brought under the authority of the College all those who practised medicine in England, with the exception of Doctors of Medicine of Oxford and Cambridge. Before this statute was enacted the College had authority only over those who practised medicine in London and seven miles round. When, however, the Medical Act of 1858 came into force, this provision in the statute was repealed, and the grade of "Members of the College" was instituted in place of the "Licentiates" and "Extra Urbem Licentiates." Under the Medical Act of 1858 a new grade of "Licentiate" was established which referred to those who passed the qualifying examination now known under the letters L.R.C.P. Dr. Slade-King was one of the last to take the "Extra Urbem Licentiate." This he did in 1857, and with his death the diploma becomes extinct—I am, etc.,

London W 1 June 26th

ARNOLD CHAPLIN

### PERINEAL DRAINAGE AND PROSTATECTOMY

SIR,—Mr. William Billington has raised (June 20th, p. 1150) a very interesting topic—namely, perineal drainage in internal urethrotomy and prostatectomy. With regard to perineal drainage in internal urethrotomy, does Mr. Billington enquire this out in all cases? Personally I feel that internal urethrotomy is an operation which has justified its existence by time, experience, and results, and should a case demand perineal drainage, then I would consider it one for external urethrotomy and not internal urethrotomy. The cases of stricture in which I have employed perineal drainage have been those complicated with severe cystitis and a type rarely seen in this country, but frequently in the East—namely, when the perineum is a mass of sinuses and fistulae and dense fibrous tissue. In the latter type external urethrotomy with drainage of the bladder is the only way by which the sinuses can be dealt with and the condition cleared up.

I have on a few occasions done median perineal lithotomy in children for stone when, owing to total lack of nursing and having the bare minimum of instruments with me, no other course was available. Necessity knows no rules, with the open desert as my operating theatre and the beautiful crystal an and "Allah" as my helpers, the results were delightful. Drainage was perfect.

With regard to perineal drainage in prostatectomy, I feel that this is adding another complication to an already sufficiently complicated operation. We must remember that an enlarged prostate is not an affection of the prostate alone, but a symptom of a generalized condition in individuals who are not only past the autumn of their days, but are fast approaching the winter.

Prostatectomy is a serious operation in the hands of even the expert, with its mortality rate nearer 20 per cent than 10 per cent, in the hands of the general surgeon the mortality must be far higher, and if perineal drainage will lower this mortality rate, then by all means let it be fully considered. I have only on one occasion used perineal drainage, and my reason for then doing so was the enormous cavity left after the removal of a big prostate with much sepsis of the bladder, but instead of cutting down on to a Wheelhouse's staff I pushed a long sinus forceps through the prostatic cavity into the perineum and

cut down upon that, using the ends to drag up the drainage tube into the prostatic cavity.

I am convinced that the mortality rate of suprapubic prostatectomy can be still further decreased by more attention being paid to the renal excretion tests. I rely on the urea excretion and phenol sulphonephthalein tests, and also very largely on the general condition of the patient himself. The subjects of prostatectomy will not tolerate long waits in cold and draughty corridors and a subsequent prolonged operation. Rapidity with the choice of a suitable anaesthetic and the production of as little shock as possible are among the many essentials for a lessened mortality rate. I have used gas and intratracheal oxygen for my last two cases, and I have been more than pleased with the complete relaxation obtained and the absence of vomiting and of post-operative shock.

SIR JOHN LYNN-THOMAS (BRITISH MEDICAL JOURNAL, June 27th, p. 1194) mentions the lower rate of mortality from the perineal operation. This may be so, but are the end-results satisfactory? The occasional drainage down to the nerve supply of the compressor urethrae muscle in this operation, with the resulting incontinence, leaves the patient in a worse condition than when he had the original disease. I have lately met with an instance of a patient who had undergone perineal prostatectomy and now spends his time going from hospital to hospital, and from surgeon to surgeon, seeking relief from this terrible affliction.

There is nothing worse from a public standpoint than to operate on doubtful subjects. In doubtful cases permanent suprapubic drainage properly done and a suitable apparatus fitted is a far better procedure than to submit many decrepit old men to the risks of so serious an operation.

I quite agree with Sir John Lynn-Thomas when he states that "we have to look out for weakness in the minute details of the plan of attack." A still greater consideration is the patient himself—I am, etc.,

### URINARY INFECTIONS

SIR,—Dr. Sangumetti (June 27th, p. 1168) discusses lavage of the bladder with a weak solution of colligol in certain urinary infections. He apparently advocates this method of treatment for acute and chronic conditions indiscriminately, for many different types of infection, and even in cases of a definitely descending character.

In acute infections vesical lavage is usually quite unnecessary and may be positively harmful. The majority of acute cases clear up rapidly, if the patient is put to bed, the bowels attended to, and the urinary tract washed out in the natural way with copious quantities of bland drinks. Potassium citrate followed by hexamine with acid sodium phosphate may be useful in some cases, while sandalwood oil has an almost magic effect if the infection is due to the staphylococci.

Lavage is undoubtedly useful in chronic infections when the bladder is not emptying itself effectually. If it is employed in chronic infections great care must be taken to exclude the possibility of the underlying condition being tuberculosis, which contraindicates irrigation.

Vesical lavage in cases of definite descending infection would appear to resemble cleaning the ball and leaving the living-rooms untouched.

When irrigation is necessary, a solution of silver nitrate is much less messy than one of colligol, and probably just as effective—I am, etc.,

London W 1 June 27th

### THE DIAGNOSIS OF PNEUMONIC PLAGUE

SIR,—The great importance of the differential diagnosis of pneumonic plague and plague pneumonia from the point of view of prognosis and prevention cannot be overestimated by workers amidst plague, as pointed out by Dr. N. A. Dree Sharp of Lagos in your issue of December 27th, 1924 (p. 1216). It is surely no satisfaction to anyone concerned with a case of the former to establish its diagnosis after the patient's death. Unfortunately, however, medical literature abounds with expressions like pneumonic plague and plague pneumonia, septicæmia

plague and plague septicaemia, that are loosely applied and held to be interchangeable. And thus confusion becomes worse confounded, inasmuch as these terms are neither identical nor interchangeable.

It is obviously forgotten that bubonic plague is essentially and primarily an infection of the lymph channels, and glands, and remains so in about 30 to 40 per cent of cases admitted to hospital in Bombay. Infection of the blood and internal organs—that is, *plague septicaemia*—occurs at a later stage in about 60 to 70 per cent, and is a secondary manifestation. So also is the advent of pneumonitis, which has been recognized as plague pneumonia.

On the other hand, septicaemic plague is a primary infection of the blood without the intervention of the lymphatic system, and is therefore a far graver infection. Here, too, pneumonitis may supervene as a secondary pneumonia, it is often mistaken for pneumonic plague in the absence of examination of the blood. True pneumonic plague, however, occurs from direct infection of the respiratory tract either from droplet infection from a patient or from a localized focus in the tonsils. I suggested the possibility of the latter mode of infection in 1909, and it was subsequently confirmed by the observations of the Plague Commission in Manchester during the epidemic of pneumonic plague in 1911.

The early diagnosis of pneumonic plague and plague pneumonia (secondary) is at times beset with considerable difficulty in the absence of physical signs during life, and also of the characteristic sputum. No amount of painstaking examination gives any indication of their presence. The physician can therefore only infer its presence on account of the prevailing epidemic. High temperature, exaggerated pulse and respiration ratio, extreme restlessness and delirium, pain and sense of constriction in the chest dyspnoea, and at times cyanosis, are the only indications to guide him or raise his suspicion. Death is rapid—within three to four days. Where, however, buboes exist the above may be considered as positive signs of plague pneumonia. The character of the sputum, when it does appear, is by no means constant. It may be purulent haemorrhagic, or pellets of coagulated blood, or bright red frothy blood-tinged mucus. Any of these characteristics may not develop till shortly before death. The clinician is thus greatly handicapped. At the autopsy, however, deep-seated and localized foci of infection or infarcts, or even solid consolidation, may be found and give pure cultures of the *Bacillus pestis*.

Prognosis, however, differs. Extensive observations at the Bombay hospitals throughout a series of epidemics have shown that cases of plague pneumonia recover to the extent of 10 to 15 per cent provided the lung infection is strictly localized. Pneumonic plague—and, for that matter, septicaemic plague also—are both equally fatal, the mortality being 100 per cent. In my experience, extending over twenty-seven epidemics of plague, I have not observed a single bacteriologically verified case of pneumonic plague recover. The single exception was one in which there existed a symbiosis with the *Bacillus pyocyaneus* in the lungs. This combination was established by frequent cultural and animal experiments with the sputum, until at last the organisms finally disappeared from it.

The above facts thus indicate that small blame should attach to any clinician if he fails to verify the presence of pneumonic plague or plague pneumonia during life. Geimino to the subject, an isolated instance of plague pneumonia causing infection of the bubonic type may be here quoted. An English plague nurse working at the Arthur Road Hospital had severe coryza with injected eyes, and was advised to rest. Whilst bending over a bubonic plague patient to feed him he happened to cough, and some sputum went into one eye. Within two days she developed parotid and cervical buboes, with considerable oedema of the neck and pharynx, oedema of the glottis soon supervened, and death occurred within five days. This case illustrates the possibility of such a contingency—

STATICS OF THE SMALL PLYVIC VISCERA  
Sir,—I am sorry that the reviewer of vol. II of my *Statics* (June 27th, p. 1176) should think it a sin for an author to believe in himself. The late Sir Henry Duthie once said to me, "If an author does not believe in himself, who can be expected to believe in him?" And, of course, no worker is going to the pains of writing a book, and much less of getting it published, unless he believes that his point of view materially and in an important manner differs from current opinion. If I am wrong in stating that "many operating gynaecologists are clearly at sea" in the matter of prolapse, I am clearly at a loss to know how I am to be taken into account by the majority of these surgeons. I am sorry, if I can be shown to be wrong I will gladly retract those statements. They were at least made in good faith. But in this respect I remind your reviewer that even as late as last April we heard in exposition on prolapse in which not only the work done on the pelvic floor musculature in this respect was completely ignored, but which imputed prolapse to merely local lesions, and consequently did not take into account the conception "that man is individual." The connective tissue hypothesis does not explain how it is that prolapse—or, as I think it would be better called, "puccendal hernia"—is related to the intra-abdominal pressure (a pressure affecting the whole individual) as other herniae, or how it is related with general metabolism, as shown by its common use in later life. But because I believe so—and show it is so—your reviewer is vexed with me.

Your reviewer accuses me of implying throughout my book that I alone know anything of prolapse. I am sorry, too, if that is so, I was not aware of it, if it be so it was not intentional. I can at least reply that your reviewer, throughout the major part of his review, seems to imply that he knows as much or more of prolapse. Yet as a reviewer he fails in his main and primary task—that of criticism. He, indeed, is critical, but it is of the author, not of the argument. Had he shown that my argument is erroneous he would have put your readers, and more especially myself, under a greater obligation—I am, etc.,

Rugby June 27th

#### BRITISH MEDICAL WOMEN IN INDIA

Sir,—Having recently been engaged in administrative work in India I can perhaps supply some of the information "Medical Woman" (June 27th, p. 1195) asks for. The population of India is so vast, and the prejudice among Indian women against the attendance of male doctors is so widespread, that the field of usefulness for women doctors is almost unlimited. Unfortunately your correspondent is right in thinking that the opportunities for British medical women are really few.

Religious prejudice and social custom in India are so strong that a newcomer, ignorant of both, and endeavouring to form a private practice, would be seriously handicapped. Moreover, owing to the poverty of the people, she could not hope to make a suitable livelihood outside the large towns.

The Women's Medical Service for India offers good prospects, but it is small and not likely to offer more than two or three openings a year for British medical women. The field in connexion with mission hospitals is larger, but the salaries are small, and special interest in mission work is, of course, required by the societies.

Other appointments are occasionally offered in connexion with Indian States and municipalities. Sometimes a European is asked for, but even then a newcomer in the country would be at a disadvantage, and the employers are usually unwilling to enter on negotiations with people at a distance, which may end in nothing, or to meet the cost of passages.

If a young medical woman had friends in a large town in India and had sufficient capital for a few years' subsistence, she might go out, and would probably be well come as an honorary worker in the women's hospital. She would thus gain experience of the language and country, and might hope to do well later in private practice.

She must however, be competent, and have some experience of her profession. Even if she does not desire private practice she is far more likely to obtain a hospital appointment if she is on the spot, has some knowledge of the country, and can be interviewed.

The Secretary of the Countess of Dufferin Fund, Delhi and Simla, is always glad to assist medical women in India with advice regarding possible openings. I believe also that some of the large women's mission hospitals are willing to appoint young British medical women as house surgeons for a year or two without permanent service. This would give excellent opportunities of acquiring knowledge of the country and tropical work.—I am, etc.,

M I BALFOUR, M.B.,  
Late Secretary of the Countess of Dufferin  
Fund India

Edinburgh June 29th

## FRACTURE OF BOTH PATELLAE BY MUSCULAR ACTION

SIR,—The cases of simultaneous fracture of both patellae reported by Mr Twistington Higgins and Mr W M Cummins in the *BRITISH MEDICAL JOURNAL* of May 30th (p 1006) and June 6th (p 1062) respectively, have reminded me of a similar case which occurred in Cairo in 1915, and which may be of interest.

I was present at an evening performance at a place of entertainment, and a dance performed by an Armenian girl was taking place. During one of the steps the girl collapsed, and it was seen that she was unable to rise and in great pain.

I was accompanied by a friend, Dr Kinnaird, and when the manager came forward and asked if a doctor was present, my friend went and attended the case. He afterwards informed me that both patellae were fractured and that he attributed the fractures to muscular action.

In spite of the almost unanimous opinion of the many Egyptian medical men who soon collected, Dr Kinnaird subsequently wired both patellae, and the woman made an excellent recovery. The "girl" in question appeared, when off the stage and devoid of make-up, to be nearer 40 than 30 years of age.

It was not noticed that great effort was made, or that the step performed at the time of the fracture demanded extraordinary exertion, and the collapse of the woman was a great surprise to the onlookers.—I am, etc.,

London W 14 June 26th

P J SIMPSON, F.R.C.V.S.

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT]

AFTER debating unemployment on June 29th, when a vote of censure on the Government was defeated, the House of Commons has devoted the rest of this week to the Widows, Orphans and Old Age Contributory Pensions Bill, which has been considered in Committee. The text of the Government's Unemployment Insurance Amendment Bill has been issued.

The Medical Committee of the House of Commons, which met on June 29th, when Dr Tiernantle was in the chair, decided to meet again specially on July 2nd to receive a report from the party of medical members of Parliament who had been to Geneva to investigate the Spallinger treatment for tuberculosis. Sir Henry Craik pointed out that announcements had appeared in the lay press describing the party as a subcommittee of the Medical Committee, and announcing that it had been favourably impressed by what it saw. The truth was that the party were not selected or deputed by the Medical Committee, and he protested against a statement having been made before the committee had received a report from the party.

The committee briefly discussed the recently issued Treasury minute on the new Committee of Civil Research, and Dr Tiernantle reported that the Prime Minister had informed him that the appointment of this committee and its work would not come under the review of the House of Commons on any estimate.

**Safety in Aviation**—Captain Guest opened a short debate on fatal accidents in the Air Force and the high premiums charged for insuring the lives of flying officers. He said the risks were taken between the ages of 17 and 28 in the main and twenty years was the extreme flying life of the average officer. Since 1922 the number of flying accidents had been about 120 and he suggested that the Government should organize a compulsory

insurance scheme. The Secretary for Air, Sir Samuel Hoare, said that, judged by the number of flying hours the number of fatal and other accidents tended to decrease every year. The policy of the Air Ministry was that every individual regularly engaged in flying duties should be supplied with an Irvine parachute, and that there should be parachutes available for each aircraft up to the full number of passengers carried besides the pilot. In addition there would be a 25 per cent supply of spare parachutes. The experience of the United States in parachutes had been instrumental in saving a substantial number of lives during the last eighteen months. The Air Ministry was issuing instructions that no parachute descents should be made in bad weather. Descents from aeroplanes were safer than from kite balloons. The Air Ministry was hurrying the delivery of parachutes. He was supplying the Life Offices Association with statistics on air risks, and hoped a reduction of the life insurance premiums for airmen would be arranged.

**Removal of Bethlem Hospital**—On the London County Council Money Bill Dr Haden Guest drew attention to the condition of the 70a Street area of North Southwark. There were 165 persons to the acre in Southwark as a whole, but the death rate had gone down from 21.4 in 1903 to 14.2 in 1924. In 1903 the death rate for the 70a Street area was 40.3 and in 1924 it was 26.6. Certain factors connected with the buildings and with the arrangement of the courts and alleys of that area made its death rate twice as heavy as in other parts of Southwark. A medical report said that the physique of the adults in the area was poor but that the children were in a better condition. To relieve congestion on this area and in Southwark as a whole there might soon be available the site of the Bethlem Hospital with an open space of 13 or 14 acres around it. The hospital authorities had decided to move to a site outside London, and to sell the Southwark site for a commercial price. They were precluded from doing that without bringing a bill before Parliament and a bill for the purpose had already been read a second time in the House of Lords. He advocated the use of the Bethlem Hospital site for the most part as a public open space and for the rest for working class dwellings. The bill was read a second time.

**Medical Services in West Africa**—On June 29th Mr Amery told Lieut Colonel A. McDouneil that the estimates for the four West African Colonies provided for a total of 246 qualified medical officers. There were at present thirty-two vacancies after allowing for selected candidates at present under instruction in tropical medicine. In the East African Medical Service which included the medical staff of Kenya, Uganda, Nyasaland, Zanzibar, Somaliland, and Tanganyika the authorized strength was 152. There were seven posts unfilled. The medical department of Northern Rhodesia had an establishment of thirteen medical officers, and there was one vacancy.

**Ambulance Service in London**—On June 29th Dr Little asked the Minister of Health if the recommendations of the Ambulance Committee of King Edwards Hospital Fund had received his consideration. Mr Neville Chamberlain replied that so far as these recommendations could be dealt with by administrative action they had been put into operation. So far as they required legislation they must await the general measure of Poor Law reform which he had in contemplation.

**Doctors Cars and Obstruction**—Mr N. McLean asked the Home Secretary whether he was aware that regulations existed which rendered doctors liable to prosecution if they left a motor car unattended in the street, and whether he proposed to issue a regulation exempting them when these circumstances arose in the course of their professional duties. Sir W. Joynson-Hicks said that medical practitioners were not exempt from the ordinary law as to driving offences, and the Minister of Transport did not think it practicable to make exceptions to the existing law or regulations in favour of any particular class of persons. The police exercised discretion in regard to prosecuting for obstruction when it was caused by a doctor's attendance on a patient. Mr McLean asked whether the Minister was aware that practitioners visiting sick patients had been summoned, and that only owing to the good sense of the magistrates were they saved from a conviction. He asked whether the Minister would not make some regulation which would enable a medical practitioner to have the particular privilege when visiting sick people of leaving his car unattended. Sir W. Joynson-Hicks said he did not think it desirable to make such a regulation. The police acted with discretion. Quite conceivably it might happen that someone was ill in Bond Street and a medical practitioner might block the whole place for a couple of hours.

**General Nursing Council**—The House of Commons has set up a Select Committee to consider the rules of the General Nursing Council on the prescribed training for nurses and the reservation of seats on the council for matrons. The Committee has power to send for persons, papers and records. Its members are Sir Richard Barnett, Sir George Berry, Mr Rhys Davies, Mr Fisher, Dr Tiernantle, Sir Charles Forrester Waller, Mr G. Hurst, Sir Richard Luce, Colonel Sinclair, Miss Wilkinson and Mr P. Wilson.

**Institutional Treatment of Encephalitis Lethargica**—In answer to Dr Haden Guest Sir Kingsley Wood said the Minister of Health was advised that no special institutional provision was required for cases of encephalitis lethargica in the acute stage. Such cases might in general be properly admitted to isolation hospitals, infirmaries or general hospitals. The provision of a special institution for the reception of children suffering from the after effects of this disease who could not be admitted to mental hospitals, was under consideration.

## Obituary.

SIR H. N. THOMPSON, KCMG, CB,  
late AMS

MAJOR GENERAL Sir Harry Neville Thompson, KCMG, CB DSO, Army Medical Staff (ret.) died at O borne on June 21, aged 64. He was the son of the late Rear Admiral Sir Harry Thompson, rector of Clonmilly, Down, and was educated at Trinity College, Dublin, where he obtained MB and ChB in 1883. Thirty-six years later he was conferred upon him the honorary degree of MD. He entered the army as surgeon on August 2nd 1884 and became colonel on November 17th, 1913 and major general on December 26th, 1917. He was in the army since 1884.

His first experience of active service was in the Nile campaign in 1898 when he received the British and Egyptian medals. In South Africa he served from 1900 to 1902, taking part in the relief of Kimberley, in operations in the Orange River, in the Tlokoeng, and in the actions of Paardeberg, Poplar, Pretoria, and Diamond Hill, and in the actions at Johannesburg. He was mentioned in dispatches in the *London Gazette* of November 15th 1901, and named the Queen's medal with two clasps. In the recent great war he went out with the original expedition to Belgium, as colonel and ADMS of the 2nd Division, and, in the retreat from Mons, remaining with the advanced field hospital, was taken prisoner, and held in Germany as a prisoner of war for six months. The hardships which he then underwent had a permanent effect on his health.

After his release he served successively as ADMS of the 48th Division, as DMS of the 6th Army Corps from May 20th 1915, as DMS of the 1st Army from July 1917 and finally as DMS of the British Army of the Rhine. He was mentioned in dispatches at least five times—in the *London Gazette* of January 1st, 1916 June 15th 1916, December 24th, 1917, May 25th, 1918, and December 30th, 1918, and received the CMC in 1916, the CB in 1918, and the KCMG in 1919. He received also the French Croix de Guerre, the American Distinguished Service Medal and the Portuguese Order of St. Aviz, of which he was a Grand Officer. He held also the Coronation and Durbu medals of 1903, and King George's Coronation medal of 1911.

We are indebted to Lieut.-General Sir William Ellis, KCB, FRCS, Director-General AMS, for the following appreciation.

The news of the death of Sir Harry Thompson will come as a great shock to the members of his old corps and will cause widespread sorrow. Throughout his service he had been one of its most outstanding and popular figures, while his gift of inspiring not only admiration, but also warm affection, earned for him an unusual number of close and lifelong friendships. The soldier never had a bitter friend, and the Royal Army Medical Corps has had few officers devoted more whole-heartedly to its interests and well-being. Sir Harry might have been regarded as expressing through his own personality the very soul of *esprit de corps* that quality so hard to define though so well understood by every soldier and, in its true significance, so misunderstood outside the army. His athletic record, his kindness of heart, and his handsome and genial presence would in themselves have ensured his popularity with his comrades but in a sense these tended to mask the sterling qualities of character which were so abundantly displayed at times when stress or emergency called for the best that was in a man. A striking personality, a gallant comrade, has left us, but he has left a memory and an example which will not readily be forgotten in the corps to which he devoted his life.

**Treatment of Yaws.**—Mr. Oimshy Gore (Under Secretary for the Colonies) told Colonel Day that he was not aware of any increase in the prevalence of yaws in East Africa but that prevalence was undoubtedly serious. Its cure by intramuscular injections of the East African Commission which also noted the delay in utilizing in Kenya the experience gained in Tanganyika. But the remedy had been in active use in Kenya for at least three years and he did not think any special action was necessary to make the preparation available in larger quantities.

**Chinies for ex-Servicemen.**—Major Tryon (Minister of Pensions) said in reply to Captain Hudson that the British Red Cross Society had intimated that it could not continue the claim for disabled men in Broad Street Holborn unless the number of pensions were increased. With the patients had to be directed of cases this was impossible and the general decline in the number to the more permanent clinics of the Ministry among others to that at Buhaga Street Millbank where the facilities for all varieties of treatment were particularly good.

**Ante-natal Work.**—The Minister of Health has stated in answer to questions (1) That of the areas mentioned by the Chief Medical Officer in his report for 1924 as showing excessive rates of infant mortality most as a result of the issue of a circular from the Ministry of Health were already taking steps to provide additional facilities for the ante-natal examination and institutional treatment of pregnant women. The medical officers of the Ministry paid special attention to these points on their visit to the areas concerned. (2) That under the existing National Health Insurance Act attendance at confinements was not included within the scope of medical benefit. The question of providing a maternity service under the National Insurance Acts had been brought to the notice of the Royal Commission on Health in 1924. The Council of the Southwark Borough Council did not provide the instance of Council received notice in 1924 that the aid of doctors was required by midwives for confinements but the London County Council supplied with 961 expectant or nursing mothers during 1924 and refused it in three cases where the income of the family was above that laid down in the scale for necessitous persons. One woman general relieving officer in Southwark is principally concerned with the parents of necessitous children.

**Veneral Disease.**—The Minister of Health informed Mr. Bennett he was aware that Colonel L. W. Harrison of the Ministry of Health had at the Congress of the Royal Institute of Public Health at Brighton on May 29th objected to the honorary secretary of the Society for the Prevention of Veneral Disease quoting from the evidence of witnesses before Lord Trevelthins Committee on the ground that that evidence was confidential. The Ministry of Health had not received from the Trevelthins Committee any request that the evidence should be treated as confidential and Mr. Chamberlain understood that it decided not to ask for publication. In reply to Sir William Davison Mr. Chamberlain said the Government had not yet decided to allocate to the Society for the Prevention of Veneral Disease a portion of the grant for propaganda and education in the prevention and combating of veneral disease.

**Ophthalmic Benefit.**—Mr. Neville Chamberlain informed Mr. Bennett that the new model scheme for the provision by approved societies of ophthalmic benefit is an additional benefit contained a provision that except in the case of renewal or repair of optical appliances the applicant for the benefit must have obtained and furnished his society with a written recommendation from a medical practitioner. Representations both from bodies representing opticians and from representatives of the medical profession including ophthalmic specialists had received due consideration.

**Shortage of R.A.M.C. Officers.**—The Secretary for War answered Major Harvey said it was impossible to deal within the limits of a parliamentary answer with the reasons which might account for the present shortage of Royal Army Medical Corps officers or with the steps the War Office was taking to find a remedy.

**Preservatives in Foods.**—The Minister of Health has stated in reply to questions (1) that the form in which the regulations giving effect to the principal recommendations of the Committee on Preservatives in Foods should be finally made is under consideration. (2) The deaths reported as due to ptomaine poisoning during the five years 1920 to 1924 numbered 32, 48, 22, 21 and 16 respectively. It was not possible to state in how many of these cases the poisoning was due to the eating of tinned foods.

**Bovine Tuberculosis.**—Figures to show the percentage of cattle in the whole country found to be tuberculous when slaughtered are not available. At the Aldgate slaughterhouses in 1924 the percentage of all bovines found to be tuberculous was 0.45 of bulls, 4.40 of calves, 0.04 of cows, 28.0 of heifers, 3.1 and of oxen 2.0. These proportions were probably below the average for the whole country. Tuberculosis is rarely found in sheep slaughtered for food.

**Votes in Brief.**  
In 1924 twelve deaths in England and Wales were returned by medical certificate or coroners inquest as due to insect bites. The Home Secretary states that provision is made under the regulations of the Workmen's Compensation Act whereby in any difficulty the referee can obtain an x-ray examination and that x-ray photographs are frequently arranged for by the medical referees. No representation has been made to him for any further provision.

L J McWELNIA, M D, M Ch, F R C P I,  
 Profes or of Pathology and Bacteriology, University College,  
 Dublin

WE announce with much regret the death, at the age of 61, of Dr L J McWeeney, Professor of Pathology and Bacteriology in University College, Dublin (National University), which took place at his home in St Stephen's Green, Dublin, after a long illness. He was a distinguished man in medical science, and his death at a comparatively early age must be regarded as a national loss.

Ldmoud Joseph McWeeney was the eldest son of the late Mr T McWeeney, at one time a prominent figure in Irish journalism. In his boyhood he gave early promise of distinction in the Catholic University in the years preceding the foundation of the Royal University, subsequently he went to the College of St Beitin at St Omer. He matriculated in the Royal University in 1881, at the first examination after its foundation. In the following year he won a university scholarship in modern languages. In 1884 he obtained his B A degree with first-class honours and, as a result, was one of the first group of graduates of the Royal University in Ireland whose academic career had begun with its foundation. During his arts course he had commenced the study of medicine, and after graduating in arts he gave his undivided attention to medicine. In 1887 he passed his M B, B Ch, and B A O examinations with honours. In 1888 he went to the University of Vienna, where he studied pathology under Rokitsanski. The following year he devoted to the study of bacteriology under Koch at Berlin. On completion of his course of study under Koch, McWeeney returned to Dublin in 1890, trained as few young Irish doctors were at that time in pathology and bacteriology. This training he put at the services of his old medical school in Cecilia Street, at which so many distinguished Irish doctors received their medical education. He took his M D degree in 1891, and three years later won the first medical studentship of the Royal University.

From 1891 to the present year Professor McWeeney was at the head of the department of pathology and bacteriology at the medical school of University College. A tireless worker, he was familiar with the scientific literature of the Continental medical centres, and his contributions to medical literature were numerous. Among the public positions which he held were those of bacteriologist to the Local Government Board, Crown analyst in Ireland, pathologist to the Mater Misericordiae Hospital, and to the Coombe and the National Lying-in Hospitals. In addition to the degrees of his own university, he held the Fellowship of the Royal College of Physicians in Ireland, the D P H of the Royal College of Surgeons, the Fellowship of the Royal Academy of Medicine, and was a member of the British Medical Association for many years.

HENRY CORBY, M D, M Ch,  
 Professor of Obstetrics and Gynaecology, University College,  
 Cork

THE death of Professor Henry Corby, M D, which took place recently at his residence in St Patrick's Place, Cork, has removed one of the foremost members of the profession in the city of Cork.

Henry Corby was born on September 27th, 1848. He was the youngest son of the late William Corby, of Cashel, co Tipperary. He entered at an early age the Queen's College, Cork, which was then one of the three constituent colleges of the Queen's University in Ireland. His first intention was to study for law, but soon after entering the Cork College he changed his mind and entered the medical school. During his time in the medical school he attended the arts lectures and took his B A degree in due course. Having pursued a distinguished medical course he received in 1875 the degrees of M D, B Ch, B A O of the Queen's University. Almost immediately after obtaining his medical degrees, he was appointed house surgeon in the North Charnitable Infirmary, Cork, and later was appointed surgeon to the same hospital. In 1883, on the resignation of Professor Macnoughton Jones from the chair of midwifery in the medical school of the

Queen's College, Cork, Dr Corby was appointed his successor, and occupied the office until his death. Dr Corby also held the positions of consulting physician to the Cork Maternity Hospital and surgeon to the South Charnitable Infirmary, Cork. He was long a member of the British Medical Association, and represented the Munster Branch on the Irish Committee.

Professor Corby was a member of the Cork Corporation, and occupied the position of High Sheriff of the city. At the various literary and scientific societies in Cork he delivered many lectures, which were subsequently published in pamphlet form. Among these were "Experiences of a House Surgeon," "Health Homes," and "Industry and Ability." In 1881 he married Katie, daughter of Thomas Coppinger-Cronin, Kerry Hall, Cork. Of the marriage there were twelve children of whom five survive, the eldest is Dr Cecil Corby of Summerhill, co. Meath. Leo, the youngest son, practised as a dental surgeon in Cashel, co Tipperary, and lost his life in very tragic circumstances while motoring to Cork during the civil strife, he failed to hear the military challenge and was shot dead.

H GRAEME ANDERSON, M D GLAS, F R C S ENG,  
 Surgical Consultant, R A F, Surgeon St Mark's Hospital

WE regret to record the sudden death, on June 28th, of Mr H Graeme Anderson, a surgeon of great ability, who had identified himself, during the war and after, with the medical and surgical aspects of aviation. While playing in a lawn tennis tournament he was seized with a heart attack and died almost at once. Only the day before he had attended, in his official capacity as consulting surgeon to the R A F, the Royal Air Force pageant at Hendon. The news of his untimely death has been received with consternation among a wide circle of colleagues and friends.

Henry Graeme Anderson was born on August 1st, 1882, the younger son of Nicol Anderson of Brailhead, Renfrewshire. After studying medicine at the University of Glasgow, at King's College, London, and at the London Hospital, he graduated M B, Ch B GLAS in 1904, obtained the diploma of F R C S Eng in 1909, and proceeded M D, with commendation for his thesis in 1919. For two years he was house surgeon, and later pathologist, to St Mark's Hospital for Cancer and Diseases of the Rectum, and he acted as clinical assistant at the Hospital for Sick Children, Great Ormond Street, and in the aural department of the London Hospital. His next posts were those of surgical registrar to the Royal National Orthopaedic Hospital, the Metropolitan Hospital, and the Cancer Hospital. On his appointment as assistant surgeon to St Mark's Hospital he began to acquire a considerable experience of rectal surgery, and in particular of the operative treatment of haemorrhoids. He published two papers on this subject in our columns before the war: the first (in 1909) gave the after-results of 300 operations, and the second (in 1913) discussed the three operations in common use at that time at St Mark's.

On the outbreak of war Graeme Anderson joined the Royal Navy as surgeon lieutenant. He was attached as surgeon to the original R N A S Expeditionary Force, and served at Antwerp and Ypres, and on the Belgian and North French coast. In 1917 he was appointed surgeon to the British Flying School at Vendome, France, and in the two following years held the corresponding post at the central R A F Hospital. He was transferred later from the Royal Navy to the Royal Air Force, with the rank of major. He was one of the small number of air medical officers who obtained a pilot's certificate at a time when this qualification was not compulsory, and he devoted much thought and research to the physical fitness of airmen, the prevention and treatment of aerial accidents, and the improvement of flying conditions. At the end of the war he was retained as surgical consultant to the R A F, and continued to give highly valued services in the treatment of aerial injuries and the selection of aviators from the surgical point of view. In January, 1918, he had contributed to the BRITISH MEDICAL JOURNAL a paper on the medical aspects of aeroplane accidents, and in March 1918,

we published a full report of a paper, read by him before the Medical Society of London, on the selection of candidates for the Air Service. In the following year appeared an excellent book on the *Medical and Surgical Aspects of Aviation*, edited and for the most part written by him when surgeon to the Royal Air Force Central Hospital, it was reviewed at some length in our issue of August 16th, 1919.

After his return to civil practice Gwynne Anderson resumed work on the staff of St Mark's Hospital, where he was promoted full surgeon, and at the Belgrave Hospital for Children, where he was senior assistant surgeon. He acted also for a time as surgical specialist to the Ministry of Pensions. With increasing experience in rectal surgery his reputation steadily grew. He contributed articles on this subject to Baughn's *System of Operative Surgery* and to the *Practitioners' Encyclopedia of Medicine and Surgery*, and was elected a member of council of the Subsection of Proctology in the Royal Society of Medicine. Last summer he contributed to our columns, jointly with Dr Cuthbert Dukes, a paper on the treatment of hemorrhoids by submucous injections of chemicals.

Gwynne Anderson leaves a widow and one daughter. At the funeral service on July 2nd, at St Columba's Church, Port Street, the Air Council was represented by Air Commodore David Munro, Medical Administrator, R.A.F., and there was a large gathering of hospital and service colleagues and personal friends.

W J J STEWART, M.D.F., D.P.H. CAMB.,  
Medical Superintendent, Willesden Municipal Hospital

We regret to record the death of Dr Stewart, medical superintendent of the Willesden Municipal Hospital, at the age of 57. He had been in poor health for some time, and his final illness was the result of influenza contracted early this year. His devotion to duty made him continue at work when wiser counsels should have prevailed. He had been in the service of the Willesden Council for the past twenty-two years, and during his period of office the hospital came to be regarded by the public and by the council as one of the best of the municipal institutions of Willesden. Dr Stewart spared himself in no way to make the public understand that the hospital was conducted in their interests and for their benefit, and that he and all the staff were entirely at their service.

William James Johnstone Stewart graduated in medicine at the University of Edinburgh thirty-four years ago, and proceeded M.D. in 1896 after obtaining the D.P.H. at Cambridge in 1895. He devoted his life to the study of infectious diseases and the administration of isolation hospitals, and he came to be recognized as one of the first authorities on these subjects in the country. During the war he was chosen by the War Office to take charge of the Adington Park War Hospital for soldiers suffering from infectious diseases. He built up and administered this large hospital in a manner which gave the highest satisfaction to both the military and civil authorities concerned, and well earned the gratitude of his country.

A colleague, closely associated with him in his work, writes: Stewart's loss will be felt keenly by all his colleagues, for he was a genial man with a kindly heart, ever ready to exert himself and take any amount of trouble to help his juniors and further their interests. Dr Stewart was one of the many silent workers in the municipal service whose works are more the subject of criticism than of praise, but who nevertheless at all times and in all circumstances perform their duties with a singleness of purpose and conscientiousness which is characteristic of the official life of this country. He leaves a widow, to whom we extend our heartfelt sympathy in her sad bereavement.

Professor H. KOSSEL, a well known hygienist of Heidelberg, has died at the age of 61.

Dr BURTON, professor of hygiene in the Lillo Faculty of Medicine, and Dr ANDERSON of the Caen Medical School, have recently died.

## Medico-Legal.

### AN ACTION FOR NEGLIGENCE

POWELL v. MAYBURY

A SPECIAL jury at the Hampshire Assizes on June 20th awarded Mr. Percy John Powell, a fancy goods dealer of Southsea, £1,000 damages against Dr. Alexander Maybury of Hampshire, for alleged improper medical treatment and negligence.

The action was tried by Mr. Justice Shearman, and counsel were for plaintiff Mr. Lyster Goddard, K.C., and Mr. W. Blake Olliver, for defendant Mr. F. B. Charles, K.C., and Mr. W. J. H. Brown.

#### The Pleadings

In the pleadings the plaintiff stated that from September to November 1921 he engaged the defendant to attend and treat him for neuritis in the right arm and alleged that such treatment was negligent and unskilful. On October 26th when the defendant was endeavouring to break down adhesions in the plaintiff's right arm while the plaintiff was under an anaesthetic the defendant dislocated the arm and broke off the lesser tuberosity of the humerus. The plaintiff alleged that Dr. Maybury used greater violence than was necessary or prudent and that the violence was negligent and unskilful. On November 1st the defendant performed an operation on the plaintiff while under an anaesthetic with the object of reducing the dislocation. The operation failed and the plaintiff alleged that, although the defendant continued to attend him up to the middle of November, the defendant took no further step to reduce the dislocation. As the result of the alleged negligence the plaintiff went into the Royal Portsmouth Hospital and underwent a further operation on November 23rd for the dislocation of the shoulder joint and his right arm was now two inches shorter than his left and he could not lift the arm away from the body. The defendant absolutely denied that he was guilty of the alleged negligence and unskilfulness, and said his treatment was proper and ordinary.

#### Plaintiff's Case

Counsel for the plaintiff said actions of this kind were serious and were brought with some reluctance because nobody liked to charge a professional man with negligence in the performance of his professional duties. But there were two sides to the question and one had to remember that they were dealing not only with the status and reputation of a professional man but also with the plaintiff, who would not bring an action of this sort without good ground and unless he had suffered severely. The defendant had been in practice for many years at Portsmouth and the plaintiff was a middle-aged man who throughout his life had been active in conducting his own business besides being a keen tennis player. During some part of his life he was troubled with pain in his shoulder which at one time was diagnosed as neuritis and also with gastric trouble. On September 17th 1921 he consulted Dr. Maybury who correctly diagnosed the gastric trouble as due to pyrosis and advised the plaintiff to have some teeth extracted. Under Dr. Maybury's advice Mr. Powell made considerable progress, and so far as the medical treatment was concerned there was no complaint. Dr. Maybury also diagnosed that the plaintiff was suffering from neuritis in the shoulder and on October 25th while under an anaesthetic there, Dr. Maybury operated to break down any adhesion which might be in the shoulder, and counsel invited the jury to say that in the course of manipulation, Dr. Maybury dislocated the plaintiff's right shoulder. It was a dislocation of some considerable extent. Counsel said that it was essential in the interests of the patient that steps should be taken to reduce the dislocation immediately. If this were left, reduction became impossible without an operation. That was what had happened in this case. Whether Dr. Maybury realized at that time that he had dislocated the plaintiff's shoulder was one of the questions the jury would have to consider. If he did not counsel then submitted he ought to have known. Something happened which caused the doctor anxiety, and that something could only have been the dislocation of the shoulder. Plaintiff was put to bed but no bandage was applied to the shoulder or to the arm. When Dr. Maybury saw the plaintiff the following evening he expressed no anxiety and did not indicate that anything upward had happened. Next morning the plaintiff found himself quite helpless in his right arm, and he could not dress himself without assistance. With Dr. Maybury's consent the plaintiff went home, where he faints and the plaintiff's daughter, a trained nurse with experience in orthopaedic cases at St. Thomas's Hospital, could not understand his collapsed state. She questioned Dr. Maybury who must at the time have had grave suspicions which he did not disclose to her. On four occasions Dr. Maybury pushed his fist under the patient's arm and applied pressure which was the recognized method adopted by surgeons for reducing an ordinary dislocation. On October 31st an x-ray photograph was taken and the plaintiff's daughter was not allowed to be present. Dr. Maybury would not allow a second opinion to be taken, but insisted on a second operation which took place in the nursing home the same two doctors being present. It was not successful, but Dr. Maybury told the plaintiff he was satisfied with the progress he was making, and that everything was going on well. Dr. Maybury refused to allow the plaintiff to see his brother, who was a doctor, but eventually the plaintiff became so dis-

satisfied that he went to Brighton to see his brother. As a result he entered Portsmouth Hospital, where Dr Smith, the house-surgeon, saw at once that his arm was dislocated, and, after an x-ray photograph was taken, an operation was performed by Mr Harold Burrows. After the time which had elapsed it was impossible to reduce the dislocation, and the arm was now shorter by two inches, which meant that the plaintiff was gravely handicapped for the rest of his life. Counsel submitted that the most skilful surgeons sometimes made mistakes, but it anything went wrong the patient expected the surgeon to tell him and take every step in his power to remedy it.

Counsel's opening was borne out by the plaintiff, but both the nursing home sister and nurse said in their evidence, that they heard nothing whatever while the arm was being manipulated.

The plaintiff's daughter in her evidence, said she told Dr Maybury that she thought her father's arm was fractured, but the reply was "No there is nothing to worry about."

Dr N R Smith said when he first saw the plaintiff's shoulder at the Royal Portsmouth Hospital it was obvious that some gross injury had been occasioned, but what it was he did not know at the time.

Mr Harold Burrows F.R.C.S., said the x-ray photograph indicated a dislocation in fact it was obvious apart from the photographs, but it was not clear how long it had been obvious. It was beyond reduction, and when he operated the humerus was dislocated and the lesser tuberosity was torn away. The tearing off of the lesser tuberosity was not recent and healing had taken place. It was not a common thing for a fracture to take place when breaking down adhesions, but he had heard of cases. It ought not to happen. After a dislocation occurred it was important to reduce it at once.

#### Defendant's Case

Counsel for Dr Maybury in opening, said the allegations were every bit as bad as a criminal matter. Dr Maybury had been in Portsmouth for forty years, was well known, and had had dozens and dozens of operation cases which had been successful during the whole of his career; there had never been a suggestion that he was negligent or unskilful. The accusations that he had not exercised the ordinary skill of a general practitioner were absolutely untrue. Was over an attack launched upon a doctor in the circumstances more unworthy, more ungenerous, than this attack? From the very first Dr Maybury attended the plaintiff who was not a rich man, with an assiduity and care that was altogether admirable. It was admitted that the medical treatment was perfectly good. The case was loaded with prejudice. If there were a fracture of the tuberosity it might just as well have been done in the hospital as out of it. Dr Maybury had not to exercise the highest skill, but he had to be reasonably careful and not go below the professional standard. A doctor could not guarantee not to make a mistake. He did not admit that there had been a mistake, but if there had been Dr Maybury would tell them that rightly or wrongly, his impression was that he got the shoulder back to justify the strapping, and he hoped and believed that there would be a reduction of the dislocation as soon as it was released the head of the bone slipped out of position. But for Miss Powell and the plaintiff's brother's interference the operation performed by Mr Burrows would have been performed by Dr Maybury. Counsel maintained that it was Mr Burrows's cutting which had hurtened the plaintiff's arm; any doctor would first try to reduce the dislocation by manipulation before doing what Mr Burrows did, the cutting was the last resource. Dr Maybury's only fault, if there was a fault, was that he was too hopeful and believed he had got the shoulder back so clamped it down and left it to set, but the condition of the shoulder was such that this was impossible.

Dr Maybury bore out counsel's opening statement, and Mr W H Battle and Mr J E Adams, consulting surgeon and surgeon respectively to St Thomas's Hospital, London, gave evidence in support of the defendant.

#### The Judge's Summing Up

Mr Justice Shearman in summing up, said it was for the jury to fix the standard of skill which they considered a patient had a right to expect from a medical man. The jury had to decide whether the defendant was guilty of negligence on October 25th. It was alleged that Dr Maybury was a bungler and was not fit to do his job; that he used violence and dislocated the shoulder through negligence. It was also suggested that the anaesthesia was incomplete, but of that there was no evidence. On the other hand it was stated that such a dislocation could arise under proper and correct treatment, and the jury had to be satisfied before finding in favour of the plaintiff that there was negligence in causing the dislocation. Another difficulty of the case was that the plaintiff said the doctor was negligent in that after the dislocation he did not discover it and immediately put it right. The defendant said he discovered the dislocation immediately it occurred and put it back at once, but the plaintiff said that was untrue and that the doctor did not know it. The dislocation having taken place the jury were asked to say that Dr Maybury did not know it until the x-ray photograph was taken, and it was suggested that not knowing was negligence. Was the defendant guilty of negligence as a surgeon on October 25th 1924 either in pushing the arm out or finding he had pushed it out in not pushing it back? If they took the defendant's view that he did his best and it was not negligence and that anybody might have done it, it was their duty to say so. The defendant claimed that he put the shoulder back and it slipped out afterwards, and that was the fault of the abnormal bone and not his fault.

The jury returned a verdict for the plaintiff as stated above, stay of execution being granted pending an appeal.

## Universities and Colleges.

### UNIVERSITY OF LONDON

#### THE UNIVERSITY SITE

At the meeting of the Senate on June 24th it was announced that the following correspondence had passed between H.M. Treasury and the University on the subject of the Bloomsbury site.

Treasury Chambers  
3rd June, 1925

Sir,

I have had before the Lords Commissioners of His Majesty's Treasury Sir Cooper Perry's letter of the 13th ulto stating that in connexion with proposals by the Delegacy and the Council of King's College for an appeal to the public for funds for new construction or endowments the Co-ordination and Developments Committee of London University desire to be informed of the answers to certain questions addressed to their Lordships in Sir Cooper Perry's letter of the 18th December last. My Lords regret that a reply to the last named letter has been delayed.

I am now to inform you (1) that the Lords Commissioners of His Majesty's Treasury are not able to hold out any hope that Parliament could be asked to contribute a larger sum than £370,000 building the Strand in the event of King's College and the Strand site reverting to the Crown.

(2) On the assumption that King's College would for their part be unwilling to move to the Bloomsbury site or unable to do so on these terms, my Lords apprehend that the University may desire to reconsider the policy of transferring their central buildings to Bloomsbury, and if the University can suggest any practicable alternative for an increase without undue cost of the accommodation for their central offices, my Lords would be prepared to consider it.

(3) My Lords are not without hope that it might be possible to make arrangements with the vendors of the Bloomsbury site whereby at least a part of it might be occupied on terms for other University purposes, but this might depend on the course of negotiations which have not been initiated.

R S MEIKLEJOHN

The Principal Officer,  
London University

University of London  
South Kensington S.W. 7,  
24th June, 1925

Sir,

I am desired to say in reply to your letter of the 3rd June that as the Lords Commissioners of H.M. Treasury have already been informed, the Senate passed a resolution in November, 1923 that in their opinion the removal and reinstatement of the secular and theological Departments of King's College on a scale adequate in the opinion of the Senate to present needs and future requirements should be effected without expense to the University or the Council of King's College in return for the surrender to the Government of the present site and buildings in the Strand. As it is certain that the expense of rebuilding King's College on the Bloomsbury site on the scale contemplated in the above resolution would far exceed the sum of £370,000 and as the Lords Commissioners of H.M. Treasury are not able to hold out any hope that Parliament could be asked to contribute a larger sum than £370,000 a reversal of value of the site and buildings of King's College in the event of reverting to the Strand in the event of themselves compelled to decline the offer contained in Mr Fisher's letter of 7th April 1920 conditionally accepted by the Senate on October 20th, 1920. Amongst the conditions laid down by the Senate was

(5) That the terms of the removal of King's College from the Strand to the Bloomsbury site shall be a matter of subsequent negotiation between His Majesty's Government, the Council of King's College and the Senate of the University, and that an agreement shall be concluded between the said parties.

It is obvious that this condition cannot now be fulfilled.

The important questions raised in paragraphs (2) and (3) of your letter will demand the anxious consideration of the Senate after reference to the relevant Councils and Committees, and to other bodies which may be interested.

The Senate note with satisfaction that the Lords Commissioners of H.M. Treasury recognize the need for increased accommodation for the central offices of the University.

E C PERRY  
Principal Officer

The Secretary,  
H.M. Treasury

#### Vice-Chancellor

Professor E. A. Gardner Litt.D. has been re-elected Vice-Chancellor for the year 1925-26.

#### Emeritus Professor

The title of Emeritus Professor of Hygiene and Public Health in the University has been conferred on Sir William J. R. Simpson, C.M.G. M.D., F.R.C.P. as from the end of the present session on his retirement from King's College after twenty-seven years' service on the closing of the Department of Bacteriology and Public Health.

## Studentship in Physiology

The University Studentship in Physiology for 1925-26 of the value of £50, and tenable for one year in a physiological laboratory of the university or of a school of the university has been awarded to Mr Isaac Cohen, PhD BSc, who will carry out research on tetulin under the direction of Professor I C Dodds at the Bland Sutton Institute of Pathology at the Middlesex Hospital Medical School

## Medical News.

The eleventh annual conference of the National Association for the Prevention of Tuberculosis will be held in London at the beginning of next week. The headquarters are the house of the Royal Society of Medicine (1, Wimpole Street, W). The morning and afternoon sessions of the first day (Monday, July 6th) will be devoted to discussions on tuberculosis in childhood. After the conference has been declared open by Sir Kingsley Wood, MP, Parliamentary Secretary to the Ministry of Health, an introductory address will be given by Professor Pirquet (Vienna) who will be followed by Dr Stanley Griffith (Cambridge) and Dr Richard Wagner (Vienna). The afternoon proceedings will be opened by Sir Robert Philip (Edinburgh), followed by Dr Clive Rintere, Professor A Louise Mellroy, and Dr Iergus Hewat (Edinburgh). At the annual meeting of the association, to be held in the evening, films will be shown, including one entitled "The Invisible Enemy." The discussion on tuberculosis in childhood will be resumed at the morning session on Tuesday, July 7th, when the opener will be Sir Henry Gauvain (Aiton), followed by Dr John Fraser (Edinburgh) and Dr Gordon Pugh. At the afternoon session addresses on the treatment of tuberculosis by sanatorium will be given by Professors Holger Voelgaard and hand Faber of Copenhagen, followed by Professor Lyle Cummings of Cardiff.

At the conclusion of the luncheon given by the staffs of the Manchester and Salford hospitals to the members of the Inter State Post Graduate Assembly of America, noted in our issue of June 27th (p 1179), Dr Charles Mayo bestowed the honorary membership of the Inter State Post-Graduate Assembly upon Sir William Milligan. On the termination of the visit to Edinburgh the officials of the Assembly expressed their satisfaction at the provision that had been made for their instruction and entertainment in that city. Dr Charles Mayo, in the name of the Assembly, conferred the honorary membership of the association upon Lord Provost Sir William Sleight, Sir Alfred Ewing, Vice Chancellor of the University, Sir Harold J Stiles, Sir David Wallace Professor Wallace, Sir Robert Philip, Professor Gulland, and Dr John D Courne.

The operations of the Hellenic Travellers' Club, founded in 1906 by the late Lord Bryce, were suspended during the war, but last spring it arranged a successful cruise, lasting sixteen days, from Venice to the Greek islands, Anzoe and Smyla Brs, and Constantinople. It has now chartered the oil burning yachting steamer *Palatino* of the Lloyd Triestino line for a cruise in the last fortnight of August and for two cruises in September, visiting Dalmatian ports as well as Greek ports. The inclusive cost will be 40 guineas, according to the berth selected. Full particulars can be obtained from the Honorary Secretary, the Rev Wilfrid Ellis, MA, Trinity College, Cambridge.

Dr T Dwyne (Lincoln's Inn), Major W V Corbett, RA MC (ret.), and Dr C N Atlee (Gray's Inn) were called to the Bar on June 24th.

The Fellowship of Medicine announces that on July 9th Mr G Grey Turner will lecture on "Gall stone disease—a pitfall for the practitioner," at 5.30 p.m., in the West Lecture Hall at 1 Wimpole Street, W. The Prince of Wales's General Hospital (North East London Post Graduate College, Tottenham, N) will hold a vacation course in medicine surgery, and the specialties from August 4th to 15th. Beginning on the same date, the All Saints Hospital will give a month's special course in diseases of the urinary system from August 24th to September 5th. The Queen Mary's Hospital, Stratford, has arranged an intensive course in medicine, surgery, and the special departments. The fee for both intensive courses is £3 3s each, or £2 2s for either week, and for the special course in urology £5 5s. Copies of the syllabus of each, together with the Fellowship programme of the general course of instruction available under its scheme, may be obtained from the Secretary at No 1, Wimpole Street, W 1.

A COURSE of lectures and practical instruction for the diploma in psychological medicine of the Universities of London, Cambridge, Durham, etc., will commence at the Bethlem Hospital, Lambeth Road, S.E. 1, on September 14th. Full particulars can be obtained on application to the Medical Superintendent.

THE Midland Branch of the Society of Medical Officers of Health, Birmingham, proposes to commemorate the knight hood conferred on the medical officer of health, Birmingham, by entertaining Sir John and Lady Robertson at a complimentary dinner at the Queen's Hotel, Birmingham, on Friday, July 10th, at 7 p.m. All members of the society are invited. The cost of the dinner will be 10s. 6d. without wine. This amount should be sent to the honorary branch treasurer, Dr. T. Ridley Bailey, at the Health Offices, Fenn Hall, Wolverhampton.

THE managers of the Pleasant Drivon Studentship in Mental Pathology announce that they have made no award this year.

THE annual general meeting of the Council of the Association of Infant Welfare and Maternity Centres will be held at Carnegie House, 117, Piccadilly, W. 1, on Tuesday, July 7th, at 3.30 p.m. The subject for discussion is heliotherapy, with Dr. Eric Pritchard in the chair. The speakers will be Professor Leonard Hill, Dr. G. I. Stehling, Dr. C. W. Sileby, Dr. Stella Churchill, and Dr. Percy Hall. Admission is free without ticket.

At the annual prizegiving of the London (Royal Free Hospital) School of Medicine for Women, on June 25th, the Dean, Dame Louisa Aldrich Blake, announced that Lord Riddell, president of the hospital, had provided for two fellowships for research in maternity and gynaecology at the Royal Free Hospital, and that Mr. Alfred Langton, chairman of the hospital, had endowed another fellowship for research in infant feeding. Dr. Mary Thomas stated that in a few months it was proposed to institute private rooms for paying patients at the Royal Free Hospital.

THE new Watford and District Peace Memorial Hospital, erected at a cost of over £65,000, was opened by H.R.H. Princess Mary, Viscountess Lascelles, on June 24th. The Bishop of St. Albans conducted the dedication service, after which Princess Mary opened the hospital door with a gold key.

THE new wards and other additions made to the Tilbury Seamen's Hospital were opened on June 24th by Viscountess Inesbroke. The Bishop of Colchester having dedicated the new buildings, the company inspected the hospital's new features, including a wing for nurses.

MRS. ELLA ROWCROFT of Torquay announced on June 25th her intention of defraying the whole cost of the erection of the new Torbay Hospital at Torquay. Mrs. Rowcroft and her sister, Miss Wills, have given £123,000 towards the new hospital, which will be begun almost immediately.

MESSRS. MAY AND BAKER, LTD., of Battersea, S.W. 11, have issued a catalogue of their pharmaceutical preparations and of vaccines for the treatment of gonorrhoea and its complications (prepared in the pathological laboratory of the London Lock Hospital). Tables of weights and volumes and of percentage solution equivalents are provided.

WE have received the first number of *La Pediatria, Archivio di Patologia e Clinica Pediatrica*, which is being issued under the editorship of Professors R. Jewmura of Naples and G. Caronia of Rome as a supplement to the fortnightly pediatric journal of the same name, the two journals being now respectively called *Archivio La Pediatria* and *Rivista La Pediatria*. The object of this new journal, which will appear at irregular intervals, is to publish works whose size and character preclude publication in existing journals except at great expense to the author. The present issue contains articles by Drs. G. Cristina and G. Caronia on the etiology of scarlet fever, accompanied by illustrations of the micro-organism which they claim to be the cause of scarlet fever, by Dr. D. Caffarella on the plurality of the antigens in the Wassermann reaction in congenital syphilis, and by Dr. M. Gerbasi on the variability of the strains of the typhoid bacillus. The price is 20 lire.

THE London School of Hygiene and Tropical Medicine, Endelsleigh Gardens, N.W. 1, invites applications for four research studentships, each of the value of £250 per annum. Applications must be sent to the Secretary by August 31st. Particulars will be found in our advertisement pages.

THE following promotions in and appointments to the Order of the Hospital of St. John of Jerusalem in England are announced—As *Knights of Grace*: Lieut. Colonel F. S. Lambert, R.A.M.C. (T); Major General Sir Samuel Guise Moors, K.C.B., C.M.G., D.I.; T. J. Waldo, Captain W. T. Wood, R.A.M.C.; Major Arnold W. Izard, M.D. As *Fringes*: Lieut. Colonel J. C. Strathearn, O.B.E., D.I.; W. C. Rigby, Dr. John Rodley, and Dr. W. H. Curse.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to *The Editor, British Medical Journal, British Medical Association House, Tavistock Square, W.C. 1*.

ORIGINAL ARTICLES and LITTEPS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C. 1 on receipt of proofs.

All communications with reference to ADVERTISEMENTS as well as orders for copies of the *Journal* should be addressed to the Financial Secretary and Business Manager.

THE TELEPHONE NUMBERS of the British Medical Association and the *British Medical Journal* are: *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange four lines).

THE TELEGRAPHIC ADDRESSES are:

EDITOR of the *British Medical Journal*, Astology Westcott, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements etc.) *Articulate Westcott* London.

MEDICAL SECRETARY, *Medicera Westcott* London.

The address of the Irish Office of the British Medical Association is 16 South Frederick Street, Dublin (telegrams *Bacillus Dublin* telephone 4737 Dublin) and of the Scottish Office 6 Drumsheugh Gardens, Edinburgh (telegrams *Associate, Edinburgh* telephone 4361 Central).

## QUERIES AND ANSWERS

### TREATMENT OF DISSEMINATED SCLEROSIS

J. R. writes to inquire about intravenous injections in the treatment of disseminated sclerosis.

The intravenous injections referred to were probably with one of the salvarsan compounds—for example sodium silver salvarsan. This treatment is founded on the belief now widely held that disseminated sclerosis is an infective disease, and on the fact that certain observers have found spirochaetes in the nervous tissues after death from this disease. It is certain that this organism is not the spirochaete of syphilis and that syphilis is not the cause of disseminated sclerosis, nevertheless treatment by salvarsan and mercury on the same lines as for syphilis is probably the best treatment we have for disseminated sclerosis. In a disease which has a marked natural tendency to remission it is extremely difficult to assess the value of any mode of treatment but the results are quite sufficiently encouraging to justify the continued use of this method if the cases are recognized at a reasonably early stage. In disseminated sclerosis as in so many diseases intravenous injections of protein—for example typhoid vaccine—have also been used either alone or in addition to salvarsan treatment.

### STUDY IN OPHTHALMOLOGY

'OPHTHALMIC' who is a graduate of medicine at present practising in one of the Dominions wishes to know what course he should pursue with a view to obtaining post-graduate study in eye work, towards which he has a strong inclination. He asks what are the facilities in London and Paris and what diploma might be obtained.

There are ample facilities for the study of ophthalmology both in London and in Paris. There is also a choice of English diplomas in ophthalmology. To name the two best known there is the diploma offered by the University of Oxford and that of the Royal College of Surgeons of England. A graduate who obtains either of these diplomas secures the full mail of high attainment in eye work. If our correspondent proposes to undertake the training necessary for the attainment of either of these diplomas his work will be mapped out by the course prescribed by the bodies issuing the diplomas. These he can obtain by inquiry from the Secretary of the Medical School, Oxford University or from the Secretary of the Royal College of Surgeons, Lincoln's Inn Fields, London, W.C. 2. The courses are very similar and require attendance on prescribed courses of study practical work and clinical work. The course is strenuous and means real work. One year's study in a recognized hospital is necessary before a candidate may enter for the examination, and in the case of the Oxford diploma two months of this year must be spent at Oxford. If he is well grounded in general medicine and has a good foundation in the physical sciences, our correspondent should have no difficulty in carrying out the prescribed course of study in the time allotted. If his ambition

do not run to the course prescribed for candidates for the diplomas, he might take up post graduate study of eye diseases and a course of refraction work at any of the British or Parisian hospitals which do post graduate work. The British hospitals are cited in the Educational Number of the BRITISH MEDICAL JOURNAL, published each year early in September, and brief notices of these same hospitals will be found in the Medical Directory under the sections devoted to hospitals and also in the advertisement pages.

#### POWER OF ENTRY BY LOCAL AUTHORITY

"R P" writes: Has an Inspector of nuisances employed by a rural district council the right of authority to demand admission into the private residence of an invalid in order to inspect the house and take measurement of rooms etc?

\* \* Section 102 of the Public Health Act, 1875, relating to nuisances, deals with the power of entry of the local authority. This Section states *inter alia*: "If admission to premises for any of the purposes of this Section is refused any Justice on complaint thereof on oath by any officer of the Local Authority (made after reasonable notice in writing of the intention to make the same has been given to the person having custody of the premises) may by order under his hand require the person having custody of the premises to admit the Local Authority or their Officer." Section 103 of the Public Health Act, 1875 states: "Any person who refuses to obey an order of a Justice for admission of the Local Authority or any of their Officers on any premises shall be liable to a penalty not exceeding £5." Having regard to these sections it is likely that the magistrates would grant an order to inspect the house, but unless it was represented to them that inspection was urgently required on account of some nuisance dangerous or injurious to health they would be unlikely to grant the order to the detriment of the sick person occupying the house. The power of the justice in this matter is discretionary.

#### INSULIN IN CANCER

"A" asks for notes of any experience of the use of insulin in inoperable carcinoma. He would welcome suggestions as to dose, the intervals between doses, and the tests necessary.

#### INCOME TAX

##### Principles of Assessment

"A M H" has purchased a practice having previously resided outside the United Kingdom, and seeks general advice.

\* \* Our correspondent should bear in mind that income tax is payable on earnings, whether realized in cash or not and that the amount of the net cash receipts can be substituted for the profits, computed on the value of the fees booked only when the circumstances justify the assumption that there will not be a substantial difference between these figures. He is liable to be assessed on the basis of the past three years' profits of the practice he has purchased, but if at the end of the year he can show that for some specific cause—for example the change of proprietorship—the profits have fallen short of the amount assessed he can claim an adjustment accordingly. There are several guides to the income tax regulations, that published by Nelsons at 2s 6d, or thereabouts, is a very useful one at the price.

##### Purchase Money

"A E S" owes his late partner a part of the purchase price of his practice and pays interest thereon, the Inspector of taxes insists on deducting this amount in calculating the income on which the earned allowance is due.

\* \* The point has not been settled by judicial authority but we should not regard "A E S's" prospects of appeal as good. In substance, "A E S" is assessed in respect of two incomes—his own earned income and the interest which he pays, and which is, in essence, income of his late partner. On this latter income he accounts for the tax to the Revenue and recoups himself for the amount so paid by deducting it from the interest when he pays his late partner. But that interest is investment income to the recipient and we fear the courts would not uphold a claim to regard it as earned income of the payer.

##### Three Years' Average

"NFLHL's" income from professional earnings has been falling and consequently his average assessment is higher than his earnings for the year of assessment. Has he any remedy?

\* \* The answer is in the negative. The special provision which authorized an adjustment was repealed after the war, and the average is now open to review only in special circumstances—for example, after a change in the proprietorship of the practice, or if an actual loss on working is incurred.

#### LETTERS NOTES ETC

Punch's contribution to the celebration of the railway centenary takes the form of a special supplement to the issue of July 1st giving a full account of his activities as a railway hero's critic, prophet and humorous commentator from 1841 down to the present day.

#### THE MEDICAL WITNESS

DR ABRAHAM ARABIAN (London, W.) writes: I have no doubt that the majority of your readers must have shared my experience of having been twitted by members of the legal profession with our traditional inability to say old unnecessarily long technical terms. And I have no doubt that they will all have shared my experience of having been confronted with that choice piece of pathological hyperbole translated by the learned judge in the case as "just a hunch." I can remember hearing it to the court of at least half a dozen occasions in the past twenty years whenever an article on the subject appears one looks for it with perfect confidence and now I see that even an eminent legal counsel selects this venerable example in his exhortation to medical witnesses to use "simple language." I confess I have always regarded the doctor who was originally responsible for this piece of evidence as a lineal descendant of Mrs Harris the choice perfection of the composition smells too much of the lamp. But it is possible that it really issued from the lips of a colleague whose accuracy and fluency were indeed to be envied if we deplored his lamentable lack of a sense of proportion. And it is equally possible that one of your readers as inquisitive and as sceptical as I, but more enterprising, can supply chapter and verse. But in any case I feel it is about time that we were entitled to receive during the course of instruction when we are to be flattered for our inability to express ourselves in "plain English," another example of what should not be said or which is quite as convincing and, if I may say so, much more probable.

#### POSTURE TO AID DELIVERY OF DETACHED PLACENTA

DR CHARLES J. HILL (Aitken, (Hilthurst near Rotherham) writes: According to Shears (*Obstetric*), "Distraction from the vagina is favoured by the lateral position. If a patient receives a vaginal douche in the dorsal position the solution is retained but if she turns upon her side the solution runs freely from the vagina. A patient delivered herself lying on her back. Thirty minutes later pressure from above failed to deliver the placenta although I felt sure it was in the vagina. The midwife suggested that the patient should turn on her side. This she did and with slight pressure the placenta was on the bed. The pelvis was roomy, the placenta small. In the dorsal position the small placenta lay in the hollow of the sacrum, posterior to the hue of pressure applied. By changing the posture of the patient the placenta was brought into the line of pressure and so was easily delivered."

#### GALL STONES IN ADOLESCENTS

"EVE, M.B." writes: May I add yet another to the already long people instance of the last few months? A schoolgirl between 13 and 14 years of age when she had suffered for a year or two for pains so that the trouble must have been present at an even earlier date. Symptoms occurred periodically, and included jaundice pain referred to the epigastrium, and a rise of temperature—sometimes to 104° F. As my condition did not respond to medical treatment and the outlook seemed desperate, a surgeon was called in. He operated as I was recovering from an exceptionally severe bout and found an enlarged gall bladder quite empty, a widely dilated common duct and a liver showing signs of impeded biliary outflow. Nature had evidently just effected a cure by the passage of a large stone. Drainage was instituted and I made an uneventful recovery, and have never had a recurrence of the familiar symptoms. I or obvious reasons I prefer anonymity, but enclose my card.

#### A WARNING

THE Registrar of the General Medical Council writes: I understand that advertisements for an assistant or a locum tenens have been answered by Mr K R G Shaw. Practitioners should be warned that before engaging him, it is desirable that inquiry as to his registration should be made at the office of the General Medical Council, 44, Hallam Street, Portland Place, London, W. 1.

#### CORRECTION

We are asked to make the following corrections in the paper on the estimation of the cardiac output as a measure of its efficiency by Dr T. Stacey Wilson, published in the JOURNAL of June 27th (p. 1167). Column 1, line 14 from foot for "a certain amount of definite elasticity" read "a certain definite amount of elasticity." Column 2, line 14 from top for "the middle line of the costal arch" read "the middle line on to the costal arch."

#### VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges and of vacant resident and other appointments at hospitals will be found at pages 32, 34, 35, 38 and 39 of our advertisement columns and advertisements as to partnerships, assistantships and locum tenencies at pages 36 and 37.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 12.

## The Mackenzie Davidson Memorial Lecture OF THE RELATIONSHIP OF RADIOLOGY AND SURGERY.

DELIVERED BEFORE THE INTERNATIONAL CONGRESS  
OF RADIOLOGY, JULY 3RD, 1925,

BY

SIR BERKLEY MOYNIHAN, Bt, F.R.C.S.,  
Leeds

It must, I feel sure, be difficult for the younger generation of physicians and surgeons fully to realize the magnitude and the high value of the help that is now given to us by the work of the radiologist. Each generation inherits the work of its forerunners, and it requires an effort of imagination denied to most of us to picture the conditions of earlier days in which many of our present resources were still undeveloped. None of us, I think, quite appreciated the difficulties against which Lister had to contend in his early investigations until we were suddenly confronted with the nauseating and startling horrors of those heavily infected wounds with which we had to deal in the first few months of the great war. And the lessons we learnt then increased, if that were possible, both the admiration we all felt for the toilsome and honest work that Lister did, and our gratitude for the imperishable heritage which he bequeathed to us.

So it is also with radiology. It requires a considerable effort of memory, and some skill in reconstruction, to recall for ourselves the days when only the note given by a sound in the bladder as it impinged against a stone made certain the diagnosis of calculus. The word "certain" is too emphatic, for I can still vividly remember Marcus Beck telling us in his ward at University College Hospital of the errors in diagnosis that might then arise when the sound struck the spine of the ischium and produced a muffled note, or when a trilet on the watch chain of the surgeon twinkled at the moment the instrument was rotated in the bladder. Nor can I easily forget the infrequency with which an exploratory operation upon the kidney revealed the presence of the stone whose existence had been confidently predicted, nor the uncertainty and ill success which attended the search for a calculus in the ureter. The change from those days, with the hesitation, the guesswork, the bitter and humiliating disappointments, to these days of confidence and precision is almost immeasurable, and it is to the devoted and skilful workers in the fields of radiology that we are grateful for the transformation. It is natural and fitting that this day should be held as a day of remembrance for one of the greatest of the pioneers—Mackenzie Davidson. It will, perhaps be appropriate if, in my role of a physician doomed to the practice of surgery, I endeavour to show, more particularly in connexion with abdominal diseases, in what degree we have taken advantage of the new methods of diagnosis and of treatment which radiology has afforded us.

### DIAGNOSIS

Let me begin with the pharynx and oesophagus, though in evening's entertainment might not unprofitably be devoted to a discussion of the value of radiology in connexion with the disorders, real or assumed, of the hidden portions of the teeth. It is true that diverticula of the pharynx were known long before the days of radiology. The first case was related in a letter from Mr Ludlow, a surgeon of Bristol, to Dr William Hunter of Glasgow and is recorded on page 85 in volume 3 of the *Medical Observations and Enquiries* of 1767. Ludlow speaks of a "preternatural bag" in the pharynx. The figures he gives are exquisite, and are unsurpassed for beauty and accuracy by any later illustrations. The specimen is in the Hunterian Museum at Glasgow to this day and a recent drawing of it shows that it has changed very little in the last 150 years.

The diagnosis of the condition in its fully developed state

is not difficult. Radiology not only makes the diagnosis quite certain, but it gives a quality of precision that could not otherwise be obtained. We learn not only that the preternatural bag is there, but we know where it lies, how large it is, what attachments it has made, and all details that may be helpful to us at the time of operation.

Of diverticula of the oesophagus we knew nothing before the days of x-ray examinations except that which was learnt from *post mortem* examinations. These little *wayside* turrets are not often of clinical importance. When filled with food they press upon and distort the tube from which they spring, and cause an uneasy suspicion as to the presence of cancer, a suspicion that only time allays.

### Oesophagus

Of the condition known as *cardiospasm* we could, of course, know nothing accurately apart from the examination made by the radiologist. It is true that our museums contain many specimens of "idiopathic dilatation of the oesophagus," but the recognition of this deformity, the knowledge of the size, position, extent, and occasions of emptying the pouch, the extent of the tube involved, and the position of the hiatus, we learn only from the screen examinations. In the first case I saw after I had just learnt of the disease from Professor Milneuz we had "washed the stomach out" many times and removed from it large quantities of fermenting, offensive, and disgusting food that had been long retained. When this little operation was repeated under the control of the x-ray we saw with amazement that the tube never entered the stomach, but lay coiled within the immense cavity formed by dilatation of the oesophagus. We failed completely to pass any bougie into the stomach though careful and repeated attempts were made. A duck-shot tied on to the end of a long piece of silk at last was seen on the screen to enter the stomach and to pass along the intestine until it emerged at the anus. When all the length of silk was entangled in the intestines and formed there a fixed point, I threaded bougies over the strand hanging from the mouth and so guided them safely into the stomach. The obstruction was fully dilated, and the patient taught to pass bougies. When she was expert the silk was cut at the mouth and at the anus, and a week later the whole length of it was vomited. Since those early days I have treated many patients, and though examinations with the oesophagoscope are made, we still rely chiefly upon the radiologist for the information which directs our treatment. There is no doubt that most of these cases were formerly regarded as malignant, and gastrectomy was done for them. A patient in the Leeds Infirmary was seen by me twenty years after this operation had been performed by Mr Ward, on the supposition that a carcinomatous growth obstructed the gullet. An x-ray examination showed the typical appearance of this disease.

The differentiation between "cardiospasm" and carcinoma now presents no difficulties, for the appearance of the oesophagus filled with an opaque medium is quite characteristic in both diseases. The large size of the oesophagus, its tolerance to food, the vigour of the peristaltic waves, which do not move the meal forward, the rounded, blunt end of the shadow which reaches to the diaphragm in cases of cardiospasm contrast as sharply as possible with the slight distension of the oesophagus, the intolerance to food, the incompleteness of the obstruction, and the narrow tapering of a shadow which is very rarely exactly on a level with the diaphragm, in cases of carcinoma.

Diaphragmatic hernia is a rare disease. Its recognition without the aid of radiology is excessively difficult or perhaps impossible. It so happens that I have had four cases in my charge—two in the time before we used the x-rays and two since. Neither of the first two was recognized until the abdomen was opened, and both were discovered with a shock of surprise. The latter two had been recognized by the radiologist, one was on the left side as most cases are, in the other the sac lay in the right side of the chest, and its contents—the stomach and the transverse colon—were easily recognized in the radiograph. I know of only one other similar case, it was operated upon by Sir Hugh Rigby.

## Ulcer of the Stomach

In connection with gastric disease it is hardly too much to say that we owe almost everything to the radiologist. As we look back upon the history of gastric ulcer in respect of its symptoms, its diagnosis, and its treatment, we must now realize that before the radiologist came to the rescue there was little that could meet with our confident acceptance. I do not doubt that more errors have been made in the diagnosis of gastric ulcer than of any other disorder. Its symptoms are mimicked with so much accuracy by other diseases that it is not only the unwary who are deceived. The radiologist has put all this right, or nearly right, and has, I think, explained the cause of the so remarkable plianism by those other diseases which arouse gastric symptoms. It is, however, not only diagnosis that has been at fault, but the treatment that has been based upon it. How can we explain the devotion of physicians to the alkali treatment of gastric ulcer except on the assumption that the diagnosis upon which such methods first were founded were erroneous? For in about 80 per cent of the proved cases of gastric ulcer the free hydrochloric acid content of the gastric juice is either normal or below normal or absent. And the surgeon is far from guiltless in the matter. He has too often been content to accept the diagnosis of "gastric ulcer," and, being, as which, unhappily, he has been led to believe is a principle for all gastric disorders and a swift and certain cure for gastric ulcer. The accuracy with which a competent radiologist, given time, can make a diagnosis of chronic gastric ulcer which the operation will confirm must in time lead to the abolition of these foolish practices by us all, and a radiology will prove the most effective remedial agency for so much of the literature and practice of days that are not yet past. May I urge once again that, until our knowledge is clarified and our practice established in reason, no diagnosis of gastric ulcer based upon clinical evidence alone be accepted as a warrant for treatment? A chronic gastric ulcer, unlike the Emperor's new clothes, is a real thing. It is to be seen, and during operation can be handled, exposed, and demonstrated. If it is there at all it is there for all to see. No gifts of vision are conferred upon the surgeon which are denied to the onlooker. If the surgeon says an ulcer is there, my competent witness can test the truth of his statement. And the accuracy of the radiologist in the diagnosis of this disease nearly approaches that of the surgeon who inspects and handles the stomach. The radiological diagnosis of gastric ulcer is not, however, constant in its accuracy. The greatest difficulties are met with when the ulcers are small, lie on the lesser curvature, are close to the cardiac orifice, and veer towards the posterior surface. The sheltered position of the part of the stomach which harbours them, the overlying liver, the barrier made by the wall of the thorax, and the impossibility of direct palpation of the stomach here, all are hindrances to the exact methods applicable to the exposed gastric area. All these difficulties are, however, in some degree surmounted if the patient is carefully watched as it enters the stomach, and if convergence of the folds of the gastric mucosa to a definite point is observed. There are times when an ulcer may be demonstrated if the filled stomach is pressed down from the epigastrium by a pad of wool, more and more increased in size, the stomach is thus rotated a little on its long axis, and an oblique or transverse view may then disclose an ulcer either. The numerous errors in diagnosis are, however, so few that the accuracy of the diagnosis made with its help is confirmed. If the diagnosis of gastric ulcer is made by no matter whom, let us agree that it is not to be retied upon by the therapist with drugs or weapons unless the radiologist confirms it. It is admittedly true that this expert may sometimes fail to see an ulcer which is undoubtedly present, especially if he is hurried in his examination by the impatience of the physician or the impatience of the sufferer himself. But, given a good chance his errors will be few, for fewer than those of any other investigator. And it must be conceded by us all that the value of any treatment

—dietetic, medicinal, or operative—cannot be gauged unless we know the precise condition for which that treatment has been prescribed. At present, with the best will in the world, I am unable to learn anything which satisfies my intelligence as to the worth of any of the methods of medical treatment in cases of gastric ulcer. And I am not often without the opportunity of seeing lamentable examples of mischances and maddlesome surgery practiced upon those who were unmistakably arranged as the victims of gastric ulcer in need of surgery. In all parts of the world operations are being practiced by those whose natural gifts may perhaps warrant their ambitions to be surgeons, but whose apprenticeship to the most superb and most difficult of all the arts has not been served with that devotion and surrender which alone equip a man for this office. I am amazed at the ready acceptance by patients of the eager ministrations of incompetent operators, when adequate skill and experience are at their command. The frequency of secondary operations when the first, being needless, yet produced effects that must now be undone, and of skilful operations for carcinoma, say of the breast which invite a quick new growth of carcinoma cells distributed over the carcass, wound, are a reproach to surgical work.

I think that the radiologist has done much to explain the reasons for the so frequent inaccuracy of the diagnosis of gastric ulcer. When we inquire as to the conditions which cause the symptoms of this disease, we who deal with the living are quick to admit that it is not only the presence of an open ulcer with its crater of varying depths, that is the responsible and immediate agent, for it is a very common experience to find an open ulcer when the symptoms are in temporary abeyance, the patient enjoying one of the "intervals" so characteristic of the disease. I believe that a state of active increase of the ulcer is essential to the production of symptoms when activity dies down and the ulcer makes its endeavor to heal all is quiet. The enlarging ulcer sets up a spasm in the stomach—the "miseria" of the radiologist. The "notch" on the greater curvature, opposite, or about exactly opposite, the "miseria" on the lesser curvature, is sometimes so deep that it seems to cleave the stomach into two parts. Watched attentively for as long a period as is safe, and examined from time to time, it appears unchanged. The conclusion at first was irresistible that an hour glass stomach existed. Yet when an operation was performed the spasm had vanished. The cause of the symptoms of an ulcer seems clearly to be in this spasm. The pain is doubtless due, in part, to the distension of the zone lying on the cardiac side of this spasm.

The occurrence of spasm is not, however, restricted to cases of gastric ulcer. There is a reflex spasm which in many of its qualities so closely resembles the direct spasm that in haste a false conclusion as to the presence of an ulcer may be drawn. The reflex spasm, even when it is as deep as the direct spasm, is rarely so constant, or so immobile. It is apt to be shallow, fugitive, changing from one part of the stomach to another, and it creeps part persuading one of the conditions so diverse as cholecystitis, tuberculous disease of the intestine or cecum, chronic appendicitis, and certain conditions of the central nervous system. No gastric ulcer, of course, exists without infection, infection may be present, too, in the pyloric part of the stomach when its primary source lies elsewhere. It is long since I described the "pyloric blush" of chronic appendicitis, and Bartholomew, these two conditions, spasm and infection, are present both in the true and in the apparent disease of the stomach, there is little wonder that the symptoms aroused by them should often lead even the alert and earnest diagnostician astray. The only competent authority to distinguish between operation between the spurious and the true is the radiologist, and, as I have before ventured to claim, his work has pride of place among the methods of diagnosis in all forms of gastric disease.

It is not only in the diagnosis of gastric ulcer that our resources have been so greatly augmented, but in the recognition of its occasional complications. Many years ago I laboured hard to discover, and in several papers elaborately described, the various signs which permitted the hopeful recognition of an hour-glass stomach. The signs

were many, the labour to elicit them protracted, the judgement difficult and not free from faults. Now the radiologist will tell us every detail that is relevant, not only is the diagnosis indisputable, but the site of the constriction, the size of the two complements of the stomach, the speed with which one or other will empty, the degree of adhesion if any—all, and even more than these, are stated with unequivocal accuracy.

#### *Cancer of the Stomach*

We shall all, I do not doubt, be prepared to concede our inability to diagnose cases of carcinoma of the stomach in an early stage. Of gastric carcinoma there are, speaking roughly, two great groups. In the one the patient has suffered for years at intervals from mild or severe forms of gastric discomfort. Finally, one attack, at first very like all the others, proves rebellious. Relief is not given by the remedies which hitherto have proved so easily successful. At the operation an ulcer, transformed in part to carcinoma, is found. In the second group are the cases I refer to as 'the bolt from the blue type'. The patient has perhaps been notorious for vigorous gastric health, he scorns the suggestion that he may perhaps have been a little dyspeptic. His denial of former ill health is disdainful to the point of arrogance. Suddenly he becomes ill, and perhaps the illness is ushered in by hæmatemesis of great severity. He loses zest for many things—food, his former activities of work or play, he loses weight, becomes anæmic, and when he is examined a lump is felt in the epigastrium. It is a melancholy but indisputable truth that, despite the activities of a small body of surgeons in this country, carcinoma of the stomach is almost always an incurable and fatal disorder. I should doubt if there are a hundred patients in the whole country who are alive and well five years after operation for the second type of carcinoma to which I have just referred. The reason for this lamentable condition of affairs lies chiefly in our incapacity, by any clinical means, to make a diagnosis in the early stage. As a profession we are not, however, blameless. We have not the courage of our experience. For when a patient over 45 begins with these insidious failures of health our tendency is to procrastinate, when we should not delay a moment. Lives are lost in part through ignorance, in part through timidity. The radiologist is now our strength. He is able, given time, to make a diagnosis of filling defects, to recognize interrupted waves of motion, of a break in peristalsis on the affected curvature, whilst the movement on the normal curvature is unchecked, of deflections of the current of the opaque meal, long before we could be in the least degree confident, by any other means at our command, of the presence of a growth. To ensure a success in treatment greater than that most meagre form we now command, two changes are essential. All patients about whom we have a doubt should be sent forthwith to the radiologist, and the x-ray examination should not be hurried.

#### *Diverticula*

What should we know of diverticula of the duodenum but for the radiologist? I have carefully searched the literature of this subject, and though the condition was first described in 1710 by Chomel, no case had been diagnosed during the lifetime of a patient before 1912. Yet J. T. Case, in a study of 6,847 consecutive patients upon whom a radiological examination of the stomach and duodenum was made, found no fewer than 85 cases of diverticulosis. Not many of the patients who possess these little wayside tracks from the duodenum suffer from them; their removal is therefore rarely necessary. But regard should be paid to them in all operations in which a diagnosis of duodenal ulcer, or of cholelithiasis, is not supported by the conditions disclosed at an operation, for the retention of foodstuffs in these cavities, or its fermentation, may cause symptoms which are apt to be ascribed to other lesions, and when these are not found on inspection the operation may, in ignorance of this condition, be abandoned as a failure.

Of diverticula of the jejunum occurring during life nothing could be known apart from their demonstration by x-ray examination. The cases are few in number, and the little pouches do not often cause much harm. This is all

to the good, for when present they are apt to affect so great a length of intestine as to make removal of the affected segment a matter of difficulty, or even impossible. The best example that has fallen within my knowledge occurred in the practice of my colleague Mr. Brithwaite, the radiological examination and the diagnosis being made by Dr. Rowden.

#### *Colon*

The subject of radiology in relation to diseases of the colon has so recently been discussed in London that I need say little concerning it to day. When I operated upon the first case recognized as diverticulitis in this country on April 2nd, 1906, so slight was our knowledge of the disease that a diagnosis during the life of the patient had never been made. Many of the specimens on our museum shelves bearing the label "carcinoma" were examples of the massive inflammatory thickening round these little crypts, and the fact that the majority of the fistulous tracks from the colon to the bladder were not due to carcinoma was generally unrecognized. The diagnosis of diverticulosis is now made with complete confidence by the radiologist, and by comparison of one radiograph with another taken some months later we are able to judge of the progress of the disease and to come to a decision as to whether operative treatment is likely to be necessary.

I have a number of patients suffering from this disease who are kept in good health, and are sheltered from the attentions of the surgeon, by medical treatment. This ensures a daily emptying of the intestine, and includes an orgy of aperients on the Saturday afternoons and Sundays which are given over, religiously, to the observance of the ritual of free and frequent evacuation. I find that operative treatment in the chronic form of this disease is rarely necessary.

The diagnosis of carcinoma of the large intestine may present such difficulties to the radiologist that great care is needed to avoid error. The opaque meal and the opaque enema both have their uses, but I find far greater help from the latter. Owing to the loading of the colon, and the tenacity with which faecal masses will adhere to the mucous membrane, some days may have to be spent in the administration of aperients and in lavage of the colon before it is empty. A small hard adherent mass of faecal material will show the same filling defect as a growth, and imprisoned gas will prevent the entry of the opaque material. Spasm of the colon, especially in heavy smokers, may suggest an organic stricture, and the overlapping of one part of the bowel by another may cause a deepened shadow or prevent a free entry of the barium mixture. I have been misled both by negative and by positive diagnosis made by the radiologist, but I have been far more often aided than hindered, especially if a day-to-day examination of the faeces for blood, when the diet is free from hæmoglobin, has been made. By collating these two methods of examination, radiological and hæmatological, with the clinical history we are able to recognize malignant disease of the colon before a tumour can be felt, and before obstruction has developed, and having regard to the fact that the colon lends itself to removal better than most parts of the body, and that recurrence after early operation is rare, this a great achievement.

#### *Gall Bladder*

The recognition of diseases of the gall bladder is now receiving help from the radiologist. In making a diagnosis we are all accustomed to speak of cholelithiasis—to say that a patient is suffering from "gall stones." But I believe that we shall be able before very long to look upon gall stones in much the same way as we now regard hæmorrhage from a duodenal ulcer, or its perforation—that is, as a quite unnecessary complication. Gall stones are the expression of tedious events in a terminal stage. Despite my friend Rosing of Copenhagen, I have unchanged belief in the view that gall stones are the consequence of infections which reach the gall bladder from one or more of several sources. Our business is to search out the inaugural symptoms, the symptoms of infection of the gall bladder, and to use all the means that the radiologist—employing, too, the method of Graham—can

bring to our aid. I look forward hopefully and not without confidence to the day when we shall regard cholelithiasis as a preventable disorder. It is true that the clinical diagnosis nowadays is not often at fault. We are able to predict the presence and the position of stones in the gall bladder or the ducts with a large measure of certainty. Even the pre-calculeous stage of this disorder is becoming day by day easier to discover. Though we can clearly see the gall stones on the radiograph in about one-third of the total number of cases in which they are shown by operation to be present, they are not often seen where they are not confidently expected. The indirect signs of cholecystitis are of more interest than the shadow of stones, for they display the changes which the disease has brought about in neighbouring organs by the presence of an enlarged gall bladder, or by the traction exerted by a shrunken gall bladder which has become adherent to them. The advantages of Graham's method would seem to be chiefly in the opportunities afforded for research into the physiological activities of the gall bladder, and into the functions of the liver. We do not yet know in what circumstances and at what rate the gall bladder fills and empties, and we have still much to learn of the secretory activities of the liver. The absence of any shadow after the Graham injection has been made is indicative of a closure of the cystic duct by a stone or by a stricture. But a mistake in the recognition of these two conditions is almost unknown. The danger attaching to Graham's present method appears to be very slight, and doubtless, with enlarging experience, will disappear. The salt used by Graham is useless as a test for hepatic efficiency owing to the fact that its colour is destroyed in serum.

The x-ray examination of the gall bladder after its removal and of the stones which it contained shows that the smaller stones almost always contain nothing but cholesterol. A very few have a nucleus, or an ingredient, of calcium. It is only after a certain size has been reached, and a chronic irritation of the gall bladder has been incessantly at work, that calcium in little spots or in a thin film is laid down on the surface of the stone.

The conclusion I draw from the radiological work done in connexion with cholelithiasis is that it enables a diagnosis to be made which would, in many instances, perhaps be in doubt, that it discovers the existence of associated lesions in neighbouring viscera, and chiefly that it is a powerful instrument of research in enabling us to discover the composition of stones, and therefore to learn something of the processes at work in their formation, and by Graham's method to add something to our very imperfect knowledge of the functions of the gall bladder and of the liver. In other conditions the help of the radiologist to the clinician is still more invaluable. In diseases of the kidney and ureter, in the discovery of stone within the bladder or of diverticula protruding from it we are even in danger of allowing our clinical diagnosis to ignore the history, and to base itself confidently upon radiology alone. No doubt others are as weak as I am. When a patient complains of pain in the loins I am tempted to ask first what the radiologist says, and to accept his word as law. Indeed, he is so constantly right when the clinician alone would be so often in doubt that here too he is both guide and governor. The use of the "bonnet" which so greatly helped us in the removal of projectiles during the war may well be remembered when the kidney, delivered from the wound, is being searched for stones. And here, too, research work upon the normal and pathological anatomy of the kidney and ureter, after opaque injections have been made, and upon the chemical constitution of stones, has added notably to our knowledge.

One of the most delightful uses to which radiology has been put is that which Sierd introduced for the localization and discovery of tumours of the spinal cord. My knowledge of this comes from Mr. Percy Sargent. I confess that I felt a thrill of pleasure when I first learnt of this most ingenious method.

#### Limitations

One very important point remains. All the methods, other than the application of our own senses directly to the patient which we so willingly use in the practice of

surgery, are after all mediocrity. They strengthen our clinical acumen by adding weapons of varied and sometimes, in the case of radiology, of immense value. But they all supplement our clinical resource, they do not, and cannot, supplant them. In regard to gastric ulcer I cheerfully acknowledge that the radiologist is, on the whole, a more competent and a more accurate diagnostician than I am. He has pride of place. But I find an occasional case when, being confident of the existence of an ulcer, I learn that the radiologist doubts, or even denies, the diagnosis which nevertheless in operation confirms. I accept with gratitude a positive diagnosis made by the radiologist but if my clinical sense urges me, after the receipt of a negative report from the x-ray department, to hold to my diagnosis, I may find my tenacity rewarded. In a long series of cases the radiologist will, however, prove to be right more often than the clinician.

When the clinical diagnosis of an ulcer, or of a diseased gall bladder, or of an ectopic growth, is not confirmed by the x-ray report, what is to be done? The whole case must once again be reviewed. In cases of gastric ulcer I hesitate to go contrary to the report of the radiologist, but sometimes I am driven by my own confidence to do so. In cases of duodenal ulcer I prefer my own opinion, linked with that of the chemist, to that of the radiologist. If he gives a negative opinion and I am persuaded of the accuracy of my own, I am prepared to act upon it. And I find I am more often right than he is. In gall bladder disease the clinician, if unsupported by the radiologist, should be prepared to act alone. I could quote many instances where patients, including medical men, have heard the diagnosis of cholecystitis from the clinician, and on learning that it lacks confirmation by the radiologist have been hilled into contentment and a dangerous inactivity, only to be roused by a very formidable catastrophe. If the careful clinician has made a diagnosis of cholecystitis or cholelithiasis a report from the radiologist that gives it no countenance should be disregarded. And so it is with suspected malignant conditions of the large intestine. Though a radiological examination often affords the greatest help when confirmed with the clinical history, and with the direct search for occult blood, the earliest and the most certain diagnosis of these diseases, after all, is made when the barrier of the abdominal wall is lifted and an

#### TUMORS

The treatment of carcinoma wherever it occurs is a disheartening business. The recognition by patients and by medical men of the earlier conditions of malignant disease, even in parts that can be seen or are easily accessible to examination, is unhappily infrequent. It seems almost incredible that patients should allow ulceration of the tongue, for example, to progress to a stage in which remedies are almost hopeless. The diagnosis presents no difficulties, and inspection of the tongue in a mirror ought surely to awaken anxiety. And at every meal time discomforts must be felt or limitations of diet be necessary. When a lump appears in the breast of a woman her natural timidity makes her perhaps, unwilling to submit herself to examination. And when the tumour is plainly felt by a medical man no little time is lost in discussions as to its nature. Nothing but the microscope can settle the diagnosis in a difficult case, to wait for the appearance of those signs which convince the surgeon that the tumour is malignant is to give time for the disease to be disseminated. A review of many cases over a period of twenty years results in this interesting law. "In tumours of the breasts of women over 40 years of age, not less than 80 per cent are malignant, no matter what the physical signs of the tumour may be." Diagnosis, therefore, is largely a matter of the age of the patient. It is a far more reliable guide than any other. Many cases follow upon chronic inflammatory lesions—in the mouth, in the breast, in the stomach, upon the skin, in the colon. Cancer therefore is often a preventable disorder. And in its early stages in most organs of the body it is a curable disorder. To the surgeon two facts about cancer appear indisputable: that it comes as a result of long continued irritation, and that it begins as a purely local disorder and can in that stage be wholly eradicated.

It is pitiable to find so large a number of cases which are inoperable, or which, having been treated by operation, suffer recurrence. To deal with these cases many remedies have been sought. Radium has proved its value in some of them, and the application of x-rays was soon included among our methods. Twenty years ago or more I sent all my breast cases, and all cases in which glands had been removed from the neck after excision of the tongue, to the radiologist. Of the effects produced by the methods of radiology in such cases it was difficult to judge. If the patient remained free from recurrence, one was unable justly to apportion credit between the radiologist and the surgeon, if the disease returned, both had proved powerless. I came tardily and reluctantly to the conclusion then that on the whole more harm than good was done, and I abandoned the method entirely.

When the deep x-ray methods were introduced I felt renewed hope, and with the most skilful and enthusiastic co-operation of Dr. Cooper I have submitted a very large number of patients to his treatment. An exposure to the deep x-ray may be made (a) before operation, (b) during operation, (c) after operation, (d) when operation is impossible.

#### (a) Before Operation

In my own practice this is not often adopted in cases of cancer, for I feel that if a growth is to be removed it may be possible to eradicate it to day and impossible to-morrow, and I never waste one single day. But in cases of carcinoma of the breast, when the activity of the growth and the rate of its extension seem almost inflammatory, it may be worth while to apply the rays, not so much to the growth as to the area around it, in the hope that the cells in lymphatic vessels, which might be set free to implant themselves upon the surface of a wound, may be destroyed.

In cases of carcinoma of the rectum, or of the uterus, with much induration and thickening around the tumour, and when adhesions appear to be present, the rays may cause a change so great as to make one doubt the truth of the earlier observations. The growth shrinks, loses its induration and fixity, and from appearing irremovable seems now to offer no difficulty. In one case in which, in an enfeebled old woman, much distressed by a teasing diarrhoea, I had performed colotomy, the growth entirely disappeared. I had removed a gland at the time of operation, and the diagnosis of carcinoma was not in doubt. No doubt the growth will reappear, but its complete removal is an evidence of the great effect which the rays are able to produce. In all cases of splenic enlargement one or more exposures to x-rays are given. The reduction in the bulk of the spleen is almost incredible from filling the whole abdomen the organ shrinks until a lump the size of a golf ball is felt below the costal margin. Then the spleen may be removed with a safety and with such ease as could not be claimed for any operation upon it in its original state.

#### (b) During Operation

In cases of Crile's operation upon the glands of the neck, and in cases of carcinoma of the breast, I think we might more often expose the entire area of operation to the rays before we close the wound. I have done this in a number of cases, and though it is impossible accurately to gauge its value, on theoretical grounds it certainly appears a very desirable procedure. I have long felt disheartened by our inability to perform more often than we do radical operations for carcinoma of the stomach. I therefore determined to enlist the help of the radiologist. The application of x-rays to the surface of the abdomen, though it may rarely do good in these cases, does sometimes appear to do him. I tried a new method. While the abdomen was opened and the stomach exposed I moved the patient to the x-ray room, and there, bringing the growth as far as possible into a widely opened wound covered by a single layer of mercurochrome gauze, I applied the lamp directly to the stomach for a period of forty minutes. The abdomen was closed. Seven weeks later in one case, nine weeks later in another, I reopened the abdomen and found the growths so changed and shrunken that I was able to remove them, with all their attached glands. Two operations of gastrectomy in this way were performed in 1923 and to-

day both patients are alive and well. One has gained 33 lb in weight, another 9 lb. In both two transfusions of blood were given—one at the time of the x-ray exposure and one before the removal of the stomach was undertaken.

#### (c) After Operation

As soon as the wound is healed after removal of the breast a course of treatment by the radiologist is now advised in all cases. The hope we entertain is that cancer cells in the neighbourhood of the wound will be killed, and that recurrence may be so prevented. Of the prophylactic value of the rays we cannot speak with any certainty. A local recurrence after an operation for mammary carcinoma is in any event so rare that a very long series of cases would be necessary to establish the value of post-operative radiation. But, again, on theoretical grounds the treatment appears so rational that I should not feel content to omit it.

It is perhaps desirable to urge once again the necessity for an x-ray examination of the chest and neck before any operation for carcinoma of the breast is undertaken. The search for metastatic deposits in outlying regions should invariably be made before removal of the primary source is undertaken. When recrudescence of the growth has taken place in the neighbourhood of the wound, or when glands appear in the neck, radiation will often produce the most remarkable results. I have known multiple nodules scattered widely over the chest wall to disappear completely, and to remain absent until the patient's death in consequence of visceral deposits, and glands grossly enlarged and causing pain in the neck and head are diminished in size or caused to vanish, and the lancinating pains soon disappear.

#### (d) Inoperable Cases

A visit to the radiological department engaged in the treatment of these cases is a depressing experience. Cases for which the surgeon can do nothing and cases for which he has done all he can, are sent to this last resort. All the surgical outcasts find refuge here. If radiology could do nothing for them no blame could attach to it, for more unpromising derelict material it would be impossible to find. Yet something is wrought upon these cases that at times approaches the miraculous. Growths shrink and wither away, and foul and extensive ulcers make vigorous attempts to heal, and haemorrhage from excavating caverns ceases entirely. Growths of the thyroid seem to melt away, and growth of the prostate, hard, fixed, and painful, may disappear very quickly. But the return is not long delayed. The most dramatic result I have ever seen was in connection with a carcinoma of the thyroid as large as the patient's head which disappeared almost entirely within a month, only to return with almost equal haste and quickly to prove fatal. There are, of course, many disappointments, and at present one is not able confidently to reckon upon any improvement in the individual case, but the fight for each one is always worth while.

The effects produced upon the patient are sometimes apt to be serious unless great care is taken. The red cells are so diminished in number that great enfeeblement results. I have many times given one or two transfusions of blood in patients who have to submit to x-ray treatment, and hypodermic injections of udon are administered regularly, and most patients are given artificial sunlight baths.

The gifts of radiology to medicine and to surgery have been most lavishly bestowed. When we consider that this science is a newcomer into the fields of diagnosis, of therapy, and of research, the results obtained in so short a time are surely matters for which humanity at large may feel profoundly thankful. If I may for one moment arrogate to myself a greater authority and a wider responsibility, I should like to offer to you, gentlemen, in the name of all your colleagues, my respectful homage for the immense benefit you and your forerunners have already conferred upon mankind, and to express my confident prediction and my warmest hopes for the continued and beneficent progress of the science which you so worthily represent.

# THE CLINICAL VALUE OF THE VAN DEN BERGH REACTION FOR BILIRUBIN IN BLOOD

WITH NOTES ON IMPROVEMENTS IN ITS TECHNIQUE

BY

J. W. McNEIL, M.D., F.R.C.P.,

DEPUTY DIRECTOR OF THE MEDICAL UNIT, UNIVERSITY COLLEGE  
HOSPITAL, LONDON,  
AND

CHRISTOPHER S. KEEFER, M.D.,

ASSISTANT IN MEDICINE, JOHN'S HOPKINS HOSPITAL, BALTIMORE

The reaction of Hujmans van den Bergh for the recognition and estimation of bilirubin in blood serum, plasma, and other albuminous fluids of the body is now well known to clinicians. More than two years have elapsed since the method was first described in the English language, and since then ample opportunity has been afforded of testing its applications in different directions.

It is not proposed to discuss here the influence of the method on research work in connexion with hepatic disease and bile-pigment metabolism, although this influence has already been great. It seems worth while, however, to reconsider, after two years, the present position and value of the test in its purely clinical aspects, and whether it has been of much service in the routine study of hepatic disease. Certain improvements in technique, which must add greatly to any merits possessed by the test, are also referred to.

During the past two years one of us (J. W. M.) has received a great deal of correspondence from workers, both in America and Great Britain, who have made use of the test. Various points of difficulty have been raised, some easily solved by the results of experience or by experiment and some not easily explainable at a distance without knowledge of the reagents used. From this correspondence, however, several important points have emerged, and require discussion.

Publications on the purely clinical application of the test are already numerous, especially in Germany. No full bibliography need be attempted, but ample records of clinical results are contained in the following:

Feigl and Querner (1919) Lepehne (1920, 1921) Rosenthal and Holzer (1921) Brühl Garban and Weissmann (1922) Andrews (1924) and Hughes (1924). Application of the test to special clinical problems has been made by Strauss and Buckmann (1922) Girard (1924) Schamberg and Brown (1924)—latent and overt salvarsan (arsphenamine) jaundice Schiff and Ehrsberg (1922)—catarrhal jaundice Fishberg (1921)—jaundice in myocardial insufficiency Andrews (1924)—peculiar diazo reaction in uraemia Brown Ames Warren, and Peabody (1925)—study of the blood pigments in pernicious anaemia.

## OTHER CLINICAL TESTS FOR BILIRUBIN IN BLOOD SERUM

Since the introduction of the van den Bergh reaction a number of other colorimetric methods for the estimation of bilirubin in blood serum have been developed, most of them designed for purely clinical use. One well known and simple method is that of Meulengracht (1921), in which the yellow serum is compared with a standard solution of potassium bichromate. By this method quantitative changes in the bilirubin content of an icteric serum are easily determined, but the presence of leucins or carotins in a serum are obvious sources of error. Moreover, the Meulengracht test is unsuitable for the detection of latent jaundice, and gives no qualitative differences such as are brought out by the van den Bergh technique. Van den Bergh has stated (1924) that after an examination by Muller (one of his co-workers) of all the simple colorimetric methods, the conclusion was reached that the original diazo method is still the best, and the present writers are in agreement with this. One other test for bilirubin in blood serum of recent introduction may be referred to here.

This method introduced by Fouchet (1918) has attracted considerable attention particularly in France and although not so delicate as the van den Bergh reaction it is said to give a positive result in a dilution of 1 in 60,000 of bilirubin. It consists essentially in mixing equal volumes of the serum with a reagent made up as follows:

Trichloroacetic acid	5 grams
Ferric chloride solution	2 c cm
Water	20 c cm

The mixture of serum and reagent is stirred with a glass rod, and in the presence of bilirubin a greenish blue colour appears. The maximum reaction is said to be obtained after twenty minutes, and an almost instantaneous coloration in concentrations of bilirubin of less than 1 in 20,000. A scale of standard units of male elute green diluted with pure white lead has been devised to give a rough quantitative method for clinical use. This test does not bear comparison with the diazo-reaction of van den Bergh for clinical purposes, but is important as affording a good and delicate confirmatory test of the presence of bile pigment in blood serum.

## DIFFICULTIES IN THE TECHNIQUE OF THE VAN DEN BERGH REACTION

In an article written by one of us (J. W. M.) in 1923 time limits for the development of different varieties of the "direct" van den Bergh reaction were given as follows:

**Prompt Direct Reaction**—Bluish violet colour, beginning immediately and maximal in ten to thirty seconds.

**Delayed Direct Reaction**—Reddish coloration, gradually deepening to become more violet, begins only after one to fifteen minutes, or even much longer.

**Biphasic Direct Reaction**—Reddish colour appears at once, and either slowly or quite rapidly deepens to violet.

These directions were founded on a moderate experience and formed an average of the results obtained up to that time. It was not expected, however, that different observers, using different reagents, would obtain results within these exact limits, and it was believed that each observer must to some extent interpret his results from his own experience. Andrews (1924), after considering the above directions and the time limit of thirty seconds given for the prompt direct reaction, states:

I have hardly ever found such a reaction and even with fresh bile the colour goes on changing after thirty seconds. If a red colour begins to appear within thirty seconds I consider that the direct reaction is positive.

One point of great importance for the development of the van den Bergh reaction has not been emphasized hitherto, but must always be considered in the interpretation of results. The interval of time between the withdrawal of blood and the carrying out of the test must be known, and should for routine clinical purposes be as short as possible—certainly not longer than two hours or thereabout. Experience has proved that serums showing a prompt direct reaction when tested at once give a slow and often long drawn-out result when retested on the following morning. This has prevented one of us (J. W. M.) from dealing with serums forwarded by post for control examination.

Differences in reaction, either to the acid or alkaline side, are of great importance for the development of the correct colour of the azo bilirubin compound. This can easily be proved after completion of the indirect reaction and addition of diazo-reagent to the supernatant fluid, by testing the effects of very dilute acid alcohol or alcoholic-ammonium hydrate on the colour developed in the test. This point emphasizes the need for care and cleanliness in the reagents and glassware employed.

The occurrence of haemolysis in a serum interferes with the colour reaction in the test, and in recent work we have used oxalated plasma only. In practice, 0.2 c cm of a 10 per cent solution of potassium oxalate is placed in a small wide loosely corked bottle, and evaporated to dryness during sterilization of the bottle. The oxalate is in this way finely distributed over a large surface, and will prevent coagulation of 10 to 15 c cm of blood, if the bottle be shaken.

## IMPROVEMENTS IN TECHNIQUE

### A Lepehne's Technique for the Qualitative Reaction

This method has simplified the reading of results in the direct reaction, since it gives standards for comparison both in respect of the rate of development and time of completion.

Three small test tubes are taken. The first or control tube contains plasma diluted with water. The third tube contains plasma in which the diazo reaction is allowed to develop and reach its maximum by the method described below. The second tube contains plasma to which diazo reagent is added last of all the character of any reaction being watched in comparison with the control tube (I) and the completed reaction (III).

Lepehne has applied an interesting observation of Adler and Strauss (1922) as an aid to completion of the reaction in tube III. These writers found when attempting to

solve the problem of the two varieties of bilirubin apparently differentiated by the diazo reaction, that the addition of a small amount of caffeine-sodium-salicylate induced in many icteric serums an increased rapidity in development of the maximal colour. They quote, for example, one serum giving a delayed reaction (16 units) only, the direct reaction being negative. Addition of a trace of caffeine-sodium-salicylate brought about a prompt direct reaction, maximal in ten seconds, while no change in colour ensued for at least two minutes in the absence of the drug. The original paper should be consulted for an account of the work leading indirectly to this observation. We have made use of caffeine-sodium-salicylate in a number of experiments, but find that the action stated above is by no means constant, at least with the samples of the drug used by us. In some serums the hastening of the colour reaction is definite, at other times no such effect was observed.

The technique of Lepelme, however, is so easy, and gives such good standards for comparison, that we recommend it strongly as the best method of carrying out the direct qualitative test.

#### Method

0.25 ccm of the oxalated plasma is placed in each of three small test tubes. To tube I (the control) add 0.2 ccm of water. Drop a small flake of caffeine sodium salicylate into tube III (shake to dissolve completely), and then add 0.2 ccm of fresh diazo reagent. In this tube a prompt or rapidly developing reaction may be obtained, quickly arriving at its maximum. Some times in our experience, the effect of the drug is negative, but in any case ample time should be allowed for the colour reaction in tube III to be completed.

To tube II then add 0.2 ccm of fresh diazo reagent watching and timing the development of any prompt or biphasic reaction in comparison with the control tube I, and the completed reaction in tube III.

#### B Improvement in the Quantitative Estimation of Bilirubin

It has always been insisted on by van den Bergh that the estimation of bilirubin made possible by the indirect reaction is by no means accurately quantitative. He states (1924) that he has always called it simply "an estimation," and not a quantitative determination. This is because some bilirubin is always carried down and lost in the albuminous precipitate during the performance of the indirect reaction. This is particularly noticed in serums giving a prompt direct reaction, where the loss may be considerable, and the precipitate coloured bright yellow. In serums giving a delayed reaction the loss is much less. Where bilirubin is present abundantly the loss can be reduced by previous dilution of the serum with water, but this method is inapplicable where only small amounts of bilirubin are present.

This difficulty has been solved by Thannhauser and Andersen (1921), who have pointed out that all the azo-bilirubin can be retained for estimation in the supernatant fluid if diazo-reagent be first mixed with the test plasma to allow "coupling" to take place, and then alcohol and saturated ammonium sulphate solution be added. In this way after shaking and centrifuging, a layer of clear ammonium sulphate solution is left at the bottom of the centrifuge tube, above this a white albuminous precipitate, and on the surface the clear reddish-violet alcoholic solution of azo-bilirubin. By this technique all the bilirubin from plasma giving a direct prompt reaction is available for estimation. This method is unnecessary for serums giving the delayed reaction only, where the loss of bilirubin in the albuminous precipitate is slight.

#### Method

The method may be summarized as follows. To 1 ccm of serum add 0.5 ccm of diazo reagent. After a minute or two add 2.5 ccm of 95 per cent alcohol and 1 ccm of a saturated solution of ammonium sulphate. Mix and centrifugize. If the colour of the supernatant fluid is too intense for quantitative estimation, dilute with alcohol 2 parts, water 1 part.

The rationale of this method need not be discussed in detail. It may be mentioned, however, that pure bilirubin is scarcely soluble in alcohol, and in the ordinary indirect reaction it is astonishing how much bilirubin remains in the alcoholic supernatant fluid after precipitation of the protein. Azo bilirubin on the other hand, is freely soluble

in alcohol. Moreover, Adler and Strauss have pointed out that in serums from cases of obstructive jaundice associated with a prompt direct reaction the globulin content of the serum is always diminished. They found that salting out the globulin fraction with magnesium sulphate hastened the development of the direct diazo reaction under experimental conditions. It seems likely that the removal of globulin, or of water, or both, by ammonium sulphate in the method suggested by Thannhauser and Andersen has something to do with the results obtained, but this question requires further investigation. In this method some water certainly goes over into the saturated ammonium sulphate solution, so that the dilution of the serum in the supernatant alcoholic solution is really slightly less than 1 in 4. For practical purposes, however, the dilution of the serum in making the estimation may safely be taken as 1 in 4.

Table contrasting the Results of the Original Method of van den Bergh (I) and the Thannhauser and Andersen Modification (II)

Disease	Type of Reaction	Bilirubin Units	
		I	II
Lost salvarsan jaundice	Direct—either prompt or biphasic	15	60
Pot salvarsan jaundice		10	55
Carcinoma—head of pancreas		30	170
Carcinoma of liver—metastatic		70	150
Catarrhal jaundice	Indirect only	45	55
Ditto—end stage		05	05

#### C Improved Standard Solution

The standard ethereal solution of monorhodanate, originally used by van den Bergh for estimation of bilirubin in "units," has always been a difficulty and source of trouble. In a review on jaundice (1923) some of the criticisms of this standard solution were briefly discussed, and it must be admitted that even when the test is carried out as carefully as possible with clean glassware and carefully prepared reagents, the colours of the test solution and of the standard may not accurately match. Slight changes in reaction of the various reagents may, as already noted, account for this, and one practical point noticed by us is that for diluting the test fluid, in order to bring it within the range of the standard solution, alcohol must be used and not water, or a change in colour tone at once ensues.

The practical difficulties with the ethereal standard solution do not end here. It must be freshly prepared for each set of estimations, and evaporation must, of course, be prevented. During the past summer Professor Højens van den Bergh has informed us of a new artificial standard solution which he and Muller have found can replace the monorhodanate ethereal solution. So far as we are aware this standard has not been published, so we wish to acknowledge its source. The new standard is made up by dissolving 2.161 grams of anhydrous cobaltous sulphate in 100 ccm of distilled water. This solution gives a colour equivalent to 1 unit of bilirubin (1 in 200,000), and is almost identical in colour with the original monorhodanate standard. It is permanent if kept in the dark, and the writers have found it entirely satisfactory in practice, and in direct comparison experiments with the original standard. The cobalt salt must be anhydrous, and at first the supply of the new cobalt standard should be compared with the old ethereal standard and any necessary adjustments in colour made. We have found slight adjustments necessary with the cobalt salt used by us. The ideal thing would be to compare the standard with the diazo-reaction given by a solution of 1 in 200,000 of pure bilirubin, but pure bilirubin is practically unobtainable.

It seems certain that this new and permanent standard must replace the older ethereal solution. If a Hellige wedge colorimeter be used one wedge can be kept full and sealed, and is then available at any time.

#### SUMMARY AND CONCLUSIONS

1 The van den Bergh reaction is the best method so far available for the clinical investigation of the bilirubin

content of blood serum or plasma. It has numerous advantages over other tests which have subsequently been proposed: (a) its extreme delicacy, (b) is not given by other yellow substances which may colour the plasma, (c) gives important qualitative distinctions between certain forms of icterus, (d) can now be used for a satisfactory quantitative estimation of bilirubin.

2. The qualitative reaction may enable a positive diagnosis of obstructive or of haemolytic icterus to be made. Pernicious anaemia, except in the stage of rapid temporary improvement, can be distinguished from secondary anaemias. In some diseases (for example, catarrhal jaundice, subacute liver atrophy, cardiac failure) the reaction may pass through all the stages from completely delayed to prompt direct, as the disease progresses. As a rule, however, in the commonest type of jaundice (the toxic and infective hepatic group) no information of any diagnostic or prognostic value is given to the clinician.

3. The test is of great practical value for the detection of "latent" jaundice.

4. Various alterations in the original technique have improved and simplified its use in clinical medicine.

## RADIOLOGY OF THE GALL BLADDER BY GRAHAM'S METHOD.

BY

HENRY COHEN, M.D.,

BRIGHT MEMORIAL RESEARCH FELLOW, HONORARY ASSISTANT PHYSICIAN,  
LIVERPOOL ROYAL INFIRMARY,

AND

R. E. ROBERTS, M.D., B.Sc., D.M.R.I.,

HONORARY RADIOLOGIST, LIVERPOOL ROYAL INFIRMARY.

It is generally admitted that the routine examination by x-rays of the gall bladder area for the presence of stones is subject to serious limitations as regards diagnostic value, for even by means of good radiographs and skilful interpretation their existence can only be clearly demonstrated in, at the outside, 35 to 40 per cent of the cases where they are present. Though an x-ray finding if positive is of definite diagnostic value, a negative finding does not exclude the presence of gall stones and must be ignored.

In the interpretation of shadows found in the gall-bladder area there are two types sufficiently characteristic to be practically diagnostic of gall stones. These are the annular or ring-like shadow (Fig 1) and the cluster of shadows resembling a bunch of grapes (Fig 2). The finding of these shadows in a radiograph of the right upper abdomen is practically certain evidence of the presence of gall stones, especially if, by radiographs taken in different positions of the body, they are shown to be situated nearer the front of the abdomen than the back. Other atypical shadows may be found in the region of the gall bladder which call for more serious thought and skill in interpretation before they can be taken as evidence of gall stones.

A large number of gall stones, however, are not sufficiently opaque to x-rays to throw any shadow at all when they are in the body. Some, indeed, are so translucent that even when the gall bladder containing them is removed and radiographed they are no more opaque than the bile or the walls of the gall bladder by which they are surrounded, in

fact, they may be even less opaque, and may show in the radiograph of the free gall bladder as translucent areas in the shadow of the more opaque gall bladder and bile.

In 1913 Holland and Williams investigated the factor underlying this varying degree of opacity of gall stone. They found that the opacity depended on the proportion of the pigment and other salts of calcium. Those containing a large proportion of cholesterol were the most translucent, while those containing a large proportion of pigment or other salts of calcium were the most opaque. The calcium salts are often deposited at the periphery of the stone and so give rise to the characteristic annular shadow.

Apart from the direct x-ray evidence of gall stone, the existence of a pathological condition of the gall bladder may often be suspected from abnormalities of contour, position, or function, of the stomach or duodenum, found during the examination of the gastro-intestinal tract by the opaque meal, or by a process of elimination, by means of x-rays, of gastric, duodenal, and appendiceal lesions, and of urinary stones.

### GRAHAM'S METHOD OF EXAMINATION.

The method of radiologically investigating the gall bladder, observations on which we wish to record in this paper, is attributable to Graham of St. Louis, U.S.A. It is based on the use of a salt opaque to x-rays which, when injected into the blood stream, is excreted by the liver, enters the gall bladder, and is there concentrated, thus rendering the gall bladder under normal conditions opaque to x-rays.

Rowntree has shown that certain dyes—for example, phenol tetra-chlorophthalen—when injected into the blood stream, are excreted almost entirely by the liver. The rate of disappearance of this dye from the blood stream has been used as a test of liver function. Graham and Cole showed that tetra-brom-phenolphthalen salts—of both calcium and sodium—were excreted by the liver almost entirely and were opaque to x-rays. The iodine compound, although more opaque, was, in their opinion, too toxic for general use. More recently Whitaker and Millen after a careful clinical and

experimental comparison of the bromine and iodine salts, state their preference for the latter. In our investigations the sodium salt of tetra-bromophenolphthalein has been used throughout. It was obtained as a crystalline powder from the Mallinckrodt Chemical Works of St. Louis.

#### Method followed in this Inquiry

Our procedure was as follows:

1 All cases were first examined radiologically by the ordinary direct method for gall stones. In every case of our series which was operated on, except one, where a doubtful and non diagnostic shadow was seen in the region of the gall bladder, the result of this examination was entirely negative.

2 The cases were then examined radiologically by Graham's method of intravenous injection of the dye. The technique adopted was as follows:

No special preliminary preparation was made except that during the four hours preceding the injection no food or fluid was allowed.

Five grams of the salt were dissolved in 40 ccm of distilled water and sterilized by boiling for twenty to thirty minutes. This solution was very slowly injected intravenously in two doses, the second being given half an hour after the first. In view of the danger of necrosis which might follow extravasation of the dye into the subcutaneous tissues, the needle was inserted separately into the median basilic vein and blood was allowed to flow freely from it before attaching the syringe. It is most important that the rate of injection should be slow if untoward symptoms are to be avoided. The injection of the dye was followed by a few cubic centimetres of sterile normal saline solution to avoid leakage of the salt when the needle was removed.

During the first day no food other than a glass of milk at lunch and in the evening was allowed. During the second day ordinary fish diet was given. For the forty-eight hours following the injection 40 grains of sodium bicarbonate were given every three hours during the day.

Two and a half hours after the injection (that is one and a half hours before the first radiographic examination) 0.5 ccm of pituitrin was given hypodermically, followed three quarters of an hour later by a simple enema.

Radiographs of the gall bladder area were taken four, eight, twenty-four and thirty-six hours after the injection.

#### Reaction following Injection

The injections occasionally gave rise to unpleasant symptoms of vasomotor shock—such as pains in the back, dizziness, nausea, vomiting, cyanosis, coldness, or "queer feelings"—associated with a lowering of the blood pressure, a preliminary rise was sometimes observed.

We have encountered no serious symptoms in our cases, only a slight reaction occurred in most of them, serious symptoms can be avoided by slow injection. If necessary a hypodermic injection of 10 minims of a 1 in 1,000 solu-

tion of adrenaline hydrochloride may be given, we have never had to use this, occasionally we have given brandy after the injection.

#### The X-ray Appearances of the Normal Gall Bladder after the Injection

The shadow of the gall bladder containing the dye, which has been excited by the liver, can be made on four to five hours after the injection has been given.

1 The shadow increases in intensity, owing to the progressive concentration of the dye, up to anything between eight and twenty-four hours. The shadow is homogeneous, oval or pyriform in shape, and of even contour. After this the shadow became less intense as the dye becomes diluted and passes out.

2 The gall bladder shadow also varies in size, being larger at the earlier examinations (five to eight hours), and then becomes gradually smaller. This variation in size is important evidence of normal distensibility and contractility of the gall bladder.

#### Physiological Requirements

Before the shadow of the gall bladder containing the dye can be produced three requirements must be fulfilled—namely:

(1) The dye must be excited by the liver. This will not take place if there be, for example, gross cirrhosis or carcinoma of the liver.

(2) The dye must be able to pass into the gall bladder. This will not take place if there be obstruction to the cystic duct or common bile duct, such as might be caused by gall stones, adhesions, papilloma, thickened bile, catarrh, etc., or if the gall bladder be filled with gall stones or growth.

(3) The dye must become concentrated in the gall bladder, by absorption from the gall bladder mucosa, contraction of the gall bladder, and retention of the dye for a sufficient length of time. This will not take place if there be chronic cholecystitis or if there be a fistula connecting the gall bladder directly with the gastro-intestinal tract and so allowing the immediate or early escape of the dye from the gall bladder.

#### The Abnormal Gall Bladder

If there is any obstruction due to gall stones, adhesions, thickened bile, etc., we may find either that the gall bladder fails to fill at all with the dye and so gives no X-ray shadow, or that it fills scantily, giving a persistently faint shadow, or that there is delayed filling.

Another evidence of pathology is marked delay of emptying, or an unduly large size of the shadow, due to loss of elasticity of the gall bladder walls. On these may be a

#### RESULTS OF INVESTIGATION

Of the series of cases in which the gall bladders were investigated by Graham's method ten were subsequently operated on and four were not operated on. Our radiological findings and deductions together with the operative or other findings are shown in Tables I and II.

In only one of the ten patients operated on were the surgeon's findings at variance with our radiological deductions. In this case (J O) the evidence obtained by an examination of the gall bladder by Graham's method (on two occasions) indicated a pathological condition of the gall bladder. Yet at operation no gross evidence of pathology was obtained. The only abnormality found was a slender adhesion over the common duct, when this had been divided the gall bladder, previously full, was seen to empty. It is doubtful whether this could be sufficient to prevent the dye from passing into and being concentrated in the gall bladder. We trust that a further examination of the gall bladder by Graham's method after the patient has recovered sufficiently from the effects of the operation may throw further light on the question.

#### CONCLUSIONS AS TO THE VALUE OF GRAHAM'S METHOD

In estimating the value of this method of radiologically examining the gall bladder three facts must be borne in mind:

- 1 That only a maximum of 35 to 40 per cent of gall stones show evidence of their presence by the ordinary method of direct radiography.
- 2 That a negative finding by the ordinary method does not exclude the presence of gall stones.
- 3 That "gall stones are incidental and not essential to a cholecystitis which may necessitate surgery."

It is therefore in those cases which by the ordinary direct method of radiography fail to show the presence of gall stones that this new method is of particular value. By no other means short of operation can we ascertain whether this negative finding signifies a normal condition of the gall bladder or not. In other words, it should be used as an adjunct rather than as an alternative to the ordinary method of examination.

A striking feature of the cases shown in Table I is the fact that of all seven cases where a pathological condition of the gall bladder was found at operation, only one case gave the slightest evidence of this before injection, whilst all gave evidence of a pathological condition when examined by Graham's method. The two cases where a definitely normal gall bladder was found at operation both gave definite indication of a normal gall bladder by Graham's method.

The single remaining case where a pathological gall bladder was deduced from the findings by Graham's method, and where at operation no gross evidence of a pathological condition was found, as already stated, needs further investigation.

However, the successes encountered in all the other cases are, in our opinion, a striking testimony to the value of this method as a diagnostic aid in the examination of the gall bladder.

We wish to express our thanks to Dr Leggate for his valuable assistance and to those physicians and surgeons of the Liverpool Royal Infirmary who have allowed us to investigate their cases.

## LEPTOSPIRA IN LONDON WATERS

By

EDWARD HINDLE, M.A. Cantab, Ph.D.,

FRSE,

MILNER RESEARCH FELLOW, LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

THE occurrence in the British Isles of sporadic cases of spirochaetal jaundice, although apparently few in number, shows that under certain conditions the disease may be acquired in this country, and therefore any observations throwing light on the origin of these outbreaks may help to eradicate the infection. The following notes on the presence of a leptospira, morphologically identical with *Leptospira icterohaemorrhagiae*, in London tap water, Thames river water, and water from several other sources in the neighbourhood, are published in the hope that they will draw attention to these interesting organisms, which under certain conditions may assume grave importance from the point of view of public health.

Attention was first directed to this subject by the discovery of leptospira in one of Professor Leiper's cultures at the London School of Hygiene and Tropical Medicine, which had been prepared to show the ciliated embryos of the broad tapeworm, *Dibothriocephalus latus*. The faeces of a patient infected with this worm, and containing large numbers of ova, had been mixed with ordinary London tap water in a Petri dish, then incubated at 30° C for sixteen days, and subsequently kept at room temperature for about one week. When examined by dark-ground illumination, the water was found to be swimming with leptospira, there being as many as thirty to forty organisms in each field of the microscope. Under the impression that the leptospira might have had a human origin, the faeces of a number of patients in the Seamen's Hospital, and also from other sources, were mixed with tap water in Petri dishes and the mixtures incubated at 25° C. In every case without exception large numbers of leptospira appeared in the water after an incubation period of ten to fourteen days. Subsequently cultures were prepared by mixing faeces with boiled tap water and incubating, when it was found that these organisms never appeared, thus showing that they were present in the water and not in the faeces. Finally, cultures were made by mixing tap water with faeces, both human and animal, which had been sterilized by boiling, and in every case leptospira appeared after incubating at 25° C for not less than ten days.

From these experiments it was evident that leptospira is present in London tap water, and an attempt was made to determine in what numbers. Although, subsequently, leptospira was found in the slime on the inside of a dripping tap in the laboratory, the direct examination of water under the microscope gave negative results, even

after centrifuging. Therefore a mixture of sterilized water and sterilized faeces was poured into a number of Petri dishes, and subsequently a measured quantity of unboiled tap water added to each, the resulting mixture was incubated at 25° C. It was found that the addition of less than 0.5 c.c.m. of tap water produced inconsistent results, whilst the addition of this amount, or more, invariably resulted in the development of leptospira. Consequently, at the time of the experiment (March) London water must have contained approximately two leptospira in every cubic centimetre.

Subsequently water from other sources was examined, and by employing the method above described leptospira were found in the following: Tring tap water, a rain-water tank in Major S. S. Flower's conservatory at Tring, and water storage tanks at a school in Buckinghamshire. In addition, these organisms were found by direct examination, in London sewage water, in Thames river water off the landing stages at Gravesend and Tilbury respectively, and in the sludge at the outlet of one of the main tanks in the aquarium of the London Zoological Gardens, which was examined through the kindness of Mr. E. G. Boulenger. Finally, my friend Dr. A. Robertson drew my attention to the presence of leptospira, in considerable numbers, in the sludge on the inside of a bowl which received the water draining from the melted ice of an ice-chest in the laboratory.

#### Culture Experiments

Up to the present I have not succeeded in isolating a pure culture of this water leptospira, and therefore it has been grown only in the presence of other bacteria. All attempts to grow it on any of the ordinary culture media used for *L. icterohaemorrhagiae* failed owing to the more rapid growth of the contaminating bacilli and cocci, which decomposed the media before there was any sign of leptospira.

By far the simplest and most successful way of growing these organisms is the coprozoic method mentioned in the earlier part of this article. A portion of human faeces about the size of a pea is mixed in a Petri dish with about 20 c.c.m. of the water to be examined and the mixture kept in the dish at a temperature of 25° to 30° C. Leptospira can generally be found after ten days, and reach their maximum growth about the twentieth day. They usually persist for a period of four to five weeks, gradually diminishing in number, until they seem to disappear, about two months after the preparation of the culture. This disappearance, however, is only apparent, due possibly to the organisms becoming so scanty that they are not easily detected. In order to produce their reappearance it is only necessary to add a small quantity of fresh faeces and continue the incubation at 25° to 30° C.

With this method the organisms can readily be obtained in considerable numbers, and it affords a convenient way of growing them for demonstration. The cultures should be kept either in the dish or in a shaded corner of the laboratory, for exposure to a bright light is rapidly fatal. It is essential to employ Petri dishes, as the same mixtures of tap water and faeces, when placed in test tubes, or flasks, and incubated at 25° C. never showed any development of leptospira. Moreover, when a culture containing large numbers of these organisms was poured into a test tube the leptospira gradually lost their motility and died off in four or five days. In parenthesis, it may be noted that this property of requiring a large surface and not growing in tubes is in marked contrast with that of *L. icterohaemorrhagiae* cultured on Wenyon-Noguchi medium, in which Dr. Okell has found that although growth takes place readily in tubes, the organism does not grow in Petri dishes or Roux bottles exposing a large surface. Obviously, it is difficult to compare the conditions when one organism is growing in association with many kinds of bacteria and protozoa, whilst the other is growing in pure culture, but the ordinary pathogenic strain of *L. icterohaemorrhagiae* may be grown in a mixture of faeces and water, and in these circumstances requires the same large surface as the water leptospira.

The luxuriant growth of leptospira in the presence of

faeces may be due to the production of sulphuretted hydrogen in the water, for Dobell<sup>1</sup> observed that this substance favoured the growth of other water spirochaetes, and the same effect has been noticed by Zucker<sup>2</sup>. These organisms will also grow in a 0.1 per cent solution of potassium nitrate in sterile tap water, but only comparatively small numbers have been obtained in this medium. The food supply of organisms growing in such a medium is a little obscure, the leptospira may obtain its nourishment either from traces of organic matter present in the water, or by synthesis of food substances from the inorganic salts. Further experiments are necessary to decide this question, which is of some interest from a theoretical point of view.

#### Filtration Experiments

The water leptospira will pass through an L3 Pasteur Chamberland filter, and may be observed by direct examination of the filtrate. With an L5 filter of the same make leptospira, as such, could not be detected in the filtrate, even after employing the centrifuge. Nevertheless, when the filtrate was poured into a Petri dish and incubated for about ten days at 25° C., leptospira appeared in the liquid. This experiment has been repeated successfully on three separate occasions, and although it is conceivable that leptospira, as such, may have been present in the filtrate in extremely small numbers, so that they were almost impossible to detect by microscopic examination, the more probable hypothesis is that the organisms were present in some other form. The L5 candle is of such fine texture that it is very difficult to believe that an ordinary leptospira could pass through, and the negative results of direct examination of the filtrate support the view that some other stage must have been present.

#### Animal Experiments

The results of these few experiments are inconclusive, as up to the present I have not succeeded in isolating a pure culture of the water leptospira, and therefore the animals have been inoculated with a mixture of organisms. In no case were leptospira recovered from the inoculated animals, except in three guinea-pigs which died the day after an intraperitoneal injection of 4 c.c.m. of a water culture. The peritoneal fluid of these animals, examined after death, contained actively motile and apparently healthy leptospira. In addition, the following results may be mentioned.

(a) Two guinea-pigs each inoculated intraperitoneally with 0.5 c.c.m. of a suspension of leptospira in water. Both showed febrile symptoms and one died on the tenth day with general darkening of the viscera but subinoculations into two other guinea-pigs gave negative results. The other individual showed rectal haemorrhages on the twelfth, thirteenth, and fourteenth days but no other symptoms.

(b) A young guinea-pig was given by mouth 4 c.c.m. of a suspension of leptospira in water. Its temperature gradually rose to 104° F. and was accompanied by epistaxis on the ninth day. Two days later it was killed and showed slight jaundice and two haemorrhagic spots on the lungs. Blood from the heart and liver was inoculated into two other guinea-pigs, both of which showed febrile symptoms and one of them had rectal haemorrhages on the seventh to the tenth days inclusive.

Owing to the necessity of bringing the investigation to a premature termination, due to the author's sudden departure for China, it has not been possible to continue these experiments, and it is doubtful whether any conclusions can be drawn from the results. Case (b) is the most suggestive, as the symptoms resembled those of a mild case of spirochaetal jaundice, and subinoculations produced fever, in one case accompanied by rectal haemorrhages. The difficulty of recovering leptospira from inoculated guinea-pigs is not sufficiently recognized by authors who have worked with exceptionally virulent strains. Buchanan<sup>3</sup> only recovered the organism from one guinea-pig out of 44 inoculated with leptospira from proved cases of spirochaetal jaundice, which shows the necessity of long-continued observations before their presence can be definitely excluded. Up to the present very little attention has been paid to the minor clinical symptoms of guinea-pigs

inoculated with leptospira, but in view of the existence of strains with varying degrees of virulence, they would probably repay closer attention.

#### DISCUSSION OF RESULTS

Although water leptospira have been recorded from various parts of the world, the only record, so far as I am aware, of their occurrence in this country is by Coles,<sup>12</sup> who found them at Bournemouth. J. G. Thomson and D. Thomson<sup>2</sup> described "a new variety of *Treponema* found in an old specimen of human faeces," which is almost certainly the organism under discussion, but assumed that it came from the faeces and not from the tap water in which the faeces had been kept. In addition, the interesting observations of Buchanan<sup>3</sup> demonstrated the existence of a free living leptospira in the slime on the roofs of coal mines in East Lothian. In the latter case, although the organisms were not discovered in surface water, there is presumptive evidence, in view of their habitat, that they are identical with the water leptospira.

Considering the variety of sources from which this leptospira has been obtained it is evidently a very widely distributed organism, and there is little doubt that further observations will result in its being found in the majority of water supplies, therefore it is of some interest to determine whether it possesses any pathogenic significance. Morphologically it is impossible to distinguish the common water leptospira from *L. icterohaemorrhagiae*, although, perhaps, too much importance should not be attached to such a resemblance in organisms presenting so few morphological characters. On the other hand, there is a biological relationship between them, for agglutination of a leptospira from London tap water was produced by a 1 in 40 dilution of an anti-leptospira serum, prepared at the Wellcome Physiological Laboratories for a virulent strain of these organisms, isolated by Buchanan. For the supply of this serum I am indebted to my friend Dr. Okell, who had used it in his researches on jaundice in dogs.

If we turn our attention to the history of recent outbreaks of spirochaetral jaundice it is obvious that there must be some very widespread source of infection in nature, for it is impossible to explain the origin of the cases in any other way. Certain outbreaks, notably that in Edinburgh described by Lyon and Buchanan,<sup>4</sup> have been traced to human carriers of the infection, and once the disease becomes established in man it seems to be contagious, especially among children. The exact mechanism of transmission in such cases is not obvious, but presumably the infection is conveyed by the urine, which often contains living leptospira. No such explanation, however, can be offered for the origin of most outbreaks, which generally seem to be associated with conditions that would favour the saprophytic growth of leptospira.

The best example of this nature is the outbreak in East Lothian, described by Buchanan,<sup>3</sup> who was able to show that certain coal mines were the source of infection. In the infected mines typical *L. icterohaemorrhagiae* were obtained from the slime on the roof, in situations that appeared inaccessible to rats. Moreover, the inoculation of this slime into guinea-pigs produced the characteristic symptoms of spirochaetral jaundice, to which the animals succumbed, and abundant leptospiral organisms were present in all their organs.

On the Continent various epidemics have been traced to insanitary bathing establishments, amongst which may be mentioned the outbreak near Magdeburg described by Kornei,<sup>5</sup> which was arrested by closing certain bathing sheds. The Vesle outbreaks in Northern France were traced to the river, and leptospiral organisms were found by Etelgeon<sup>6</sup> in the river water and mud. During the great war epidemics of the disease occurred in wet ill drained trenches, where conditions, especially in dug outs, would undoubtedly favour the growth of leptospira.

The disease has also been recorded from among workers in sewers, or, in one or two cases, in persons who had fallen into filthy water.

The best example of such a case is that described by Manson-Bahr<sup>7</sup> of a seaman who fell into the Thames off Gravesend, and was nearly drowned. Five days later he developed a typical attack of spirochaetral jaundice, and

Wenyon and Brown, who made a laboratory examination of this case, were able to recover the leptospira from guinea pigs inoculated with the patient's blood. A subsequent examination, recorded in the earlier part of this paper, supports Dr. Manson-Bahr's view that the infection had originated from immersion in contaminated water, for I found the Thames water at Gravesend to contain as many as one leptospira in every 40 fields of the microscope.

The work of Zuelzer<sup>8</sup> and others on water leptospira shows that non-pathogenic forms may acquire pathogenic properties after prolonged culture, although Buchanan<sup>3</sup> is the only observer who has succeeded in finding virulent leptospira living saprophytically in nature.

The occurrence of a similar infection in wild rats, in which the organism can exist as a harmless commensal, has led to the view that they may serve as a reservoir, and in view of the usual habitat of these animals it seems reasonable to assume that they acquire the infection by drinking filthy water containing leptospira. The observations of Foulerton,<sup>9</sup> Stevenson,<sup>10</sup> and Balfour<sup>11</sup> show that a considerable proportion of London rats are infected with the disease, Balfour<sup>11</sup> finding leptospira in 22.6 per cent of 154 brown rats. Since the organisms are passed out in the urine, these animals may serve to spread the infection, but their agency is not essential, as outbreaks have occurred in which their presence was definitely excluded.

Considering all the known facts concerning outbreaks of spirochaetral jaundice, there is reasonable evidence for the assumption that certain strains of water leptospira may acquire pathogenic properties, and therefore constitute a potential source of human infection. The conditions under which they acquire such properties are not clear, but one important factor is the dose, as the results of inoculation experiments with the water leptospira, as well as with blood spirochaetes, have shown that it is necessary to introduce a minimal number of organisms in order to produce infection. For example, Buchanan<sup>3</sup> failed to infect guinea-pigs by the inoculation of 1 c.c. of slime containing leptospira, but with four times this amount produced fatal infections. On the other hand, the occurrence of laboratory infections among experienced bacteriologists, who have worked with this disease in guinea pigs, suggests that after passage through these animals the virulence for man is considerably increased, and it is possible that similar variations may occur in nature.

The susceptibility of the host is another important factor, for the inoculation of identically the same dose into a number of guinea-pigs produces very different results, ranging from a complete absence of any obvious effects up to the development of a fatal attack of intense haemorrhagic jaundice. Probably the human host is equally variable in susceptibility to infection, and it is a noteworthy feature that most of the recent outbreaks of the disease have been confined to children or young adults.

The presence of leptospira in water in small numbers is obviously harmless, otherwise a considerable proportion of the population would be affected, but under insanitary conditions, and especially when faecal contamination of the water takes place, the organism may increase in numbers and constitute a real source of danger. Under modern sanitary conditions there is little likelihood of the disease assuming any great importance, but under abnormal conditions, such as war, or in countries where sanitation has not yet developed, the infection is likely to continue, as the causative agent is evidently capable of living indefinitely as a saprophyte, either in water or in damp localities containing suitable organic matter. Spirochaetral jaundice may be added, therefore, to the long list of diseases which owe their origin to insanitary conditions and lack of attention to public hygiene.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL.

#### REMOVAL OF AN OVARIAN CYST IN AN AGED WOMAN RICHMOND

15 November, 1923, I was asked by a colleague to tap an ovarian cyst. The patient was an old lady who had previously refused operation for various reasons. The necessity for tapping became more and more frequent, and on each occasion from 16 to 18 pints of thick glaucous fluid were drawn off. The last interval between paracenteses was three weeks. The old lady declared that her life was not worth living with the continuous discomfort of pressure symptoms, and said she would rather be operated on and die under the anæsthetic than endure it any longer. After a lengthy discussion with the patient's doctor I decided to take the risk and make an attempt at permanent relief. I said that if I could not remove the tumour in its entirety in a given time I would not proceed further with the operation. My only fear was that it might be malignant. I tapped the cyst for the last time on May 3rd, and operated exactly one week later.

The operation was performed on May 10th, when the patient was 90 years of age. The usual midline incision was made, and I found a large multilocular ovarian cyst with multiple adhesions to the peritoneum, but fortunately these could easily be broken down by the hand and did not require ligature. The pedicle was clamped, ligatured, and the cyst removed whole. It was not malignant, and contained over a gallon of fluid. The operation took twenty-five minutes.

The patient sat up in a chair on the seventeenth day, and walked from one room to another on the twenty-second day. To use a familiar and unscientific expression, "she did not turn a hair," and continues to enjoy good health. This case may not constitute a record, but it is sufficiently unusual to warrant publication.

JOHN W. HEEVES, B.S., M.B. Lond.,  
Surgeon Royal Hospital Richmond,  
and Richmond Infirmary.

#### SEVERE GENERALIZED DERMATITIS AFTER A LOCAL SCALD

The case of severe dermatitis following ultra violet light reported by Drs. MacCormac and McCler (April 11th, p. 695) is interesting and instructive. Recently I had a case presenting many points in common, but caused by scalding. A lady, aged 55, scalded one foot and instep (probably a scald of the second degree), which was treated rather casually with home remedies, no doctor was called in, and no serious attempt was made to keep the part aseptic. Putrid healing occurred after some months, but then the condition became worse and spread over the body. When I first saw her, three months after the accident, the affected foot was acutely inflamed and there were extensive raw areas—copiously weeping. The other foot was similarly but less severely affected. There was a generalized acute eczematous dermatitis all over the chest, trunk, legs, and arms, with considerable pruritus, the face alone escaped. In ten days, with aseptic treatment of the foot and soothing applications to the rest of the body, and mistura alba, the condition completely cleared up. There was no previous history of eczema, no doubt the generalized dermatitis was produced by toxic absorption from the scalded foot.

#### A NOVEL METHOD OF REDUCING A DISLOCATION OF THE ELBOW

A BRITISH sailor came into the Cottage Hospital at Algiers recently with a typical dislocation of the right elbow, the forearm being displaced forwards. It so happened that Professor Curtillet, surgeon to the Civil Hospital, was in the

hospital—a circumstance which enabled me to watch the reduction of the displacement by what appeared to me to be a novel method.

Standing on the right side of the patient, who was in the erect position, he grasped the patient's right arm firmly above the elbow with both hands, leaving the forearm free. Having raised the limb to an obtuse angle with the trunk he then, suddenly, taking the patient quite by surprise, imparted to the limb a violent flail-like movement, whereupon the displaced forearm slipped back into its place. The pain was no doubt considerable, indeed, the patient collapsed and fell to the ground, but it was only momentary, for he got up smiling. Dr. Curtillet told me he had employed this method many times with invariable success, and it is so simple that it deserves to be more commonly known.

Alger.

ALFRED S. GLENN

#### PLUGGING THE POSTERIOR NARES

The customary method of plugging the posterior nares in operations by the use of a catheter or of Belloq's sound has several disadvantages. The use of a forehead mirror is almost essential, and, when the hæmorrhage is severe, it may be impossible even to see the thread. In a case where the Belloq sound failed the following method was successful.

One end of a piece of packing tape was twisted several times round the tip of the forefinger, which was put into the mouth and pushed up behind the palate into the nasopharynx. With snare forceps introduced through the nose the tape was then easily seized and drawn out through the anterior nares. A roll of gauze was attached and secured in position in the usual manner.

This method, being carried out by the sense of touch alone, can be employed where a suitable light is not available, or where the view of the pharynx is obscured by blood. In such circumstances the method, which I believe to be new, may prove useful.

HENRY S. RUSSELL, B.Sc., M.B., Ch.B.,  
Barrow-in-Furness. Head Surgeon North London Hospital.

#### FACIAL FISTULA OF THE SCROTUM

The case here recorded was shown to the Sierra Leone Branch of the British Medical Association as an interesting case, showing the vitality and resistance to sepsis of some of the natives.

A man aged about 46 was admitted to the Connaught Hospital, Freetown, Sierra Leone, on November 22nd 1924 complaining of a wound in the leg. He was found also to have a facial fistula of the scrotum with a large right inguinal hernia in a much enlarged scrotum. The opening was about three quarters of an inch in diameter and could be probed to a depth of two inches. The patient stated that about eighteen months previously he had been stabbed with a knife while at work on his farm, but there is a suspicion that the wound was inflicted while engaged in burghling as he was known to be a burglar. Very seldom had he used rectum or anus since that time. All faeces passing by the fistula.

An operation was performed by Dr. J. Y. Wood of the West African Medical Staff, assisted by Dr. E. J. Wright and the writer.

As there did not appear to be much adhesion at the external ring an incision two inches long was made just below this with a view to cutting across the loop making an end to end anastomosis and performing a radical cure for hernia. This was found to be impossible owing to adhesion and the wound was closed. A fresh incision was then made above the fistula and enclosing the latter elliptically. The bowel proved to be the cæcum much dilated and not a double loop. One side was embedded in a dense mass of hard fibrous tissues from which it could not be freed. It was found possible however, by careful dissection to free the sac below the mass. The base of the fistula was then cut across by a second elliptical incision—the edge in the fibrous mass being freed sufficiently to catch it with stitches. A row of continuous sutures closed the aperture about two inches long in the bowel. A second row stitched down a fold of the outer coats over this. A third row of interrupted sutures massed the sac over this and the wound in the scrotum was closed. The wound healed by first intention the first dressing not being removed for ten days during which time the patient remained on fluid diet. On the third day after operation the bowels acted naturally, and continued to do so, a purge being given on the tenth day. He was discharged on the eighteenth day completely cured but still with a scrotal hernia, the scrotum at the site of the operation was soft and pliable and the fibrous mass had practically disappeared.

W. F. OUMIRI, TUTOR  
Connaught Hospital, Freetown, Sierra Leone.

AN INDIGINOUS OPERATION FOR STRANGULATED  
HERNIA

Medicine is to some extent spread throughout Mohammedan communities in Northern Nigeria. The physician is the *malam*, or learned man, and the main part of his practice consists in selling amulets and prescribing draughts of water in which are dissolved the ink used to write a sentence of the Koran. The surgeon, represented by the *haiber*, deals with abscesses and wounds, and cures, while the greater part of his work is very crude, it is often founded on sound common sense and occasionally has quite brilliant results, as evidenced in the following case.

Yesufu a Hausa native of Kano province aged about 40 consulted me with regard to a faecal fistula. He said that three years ago a swelling which had come down into his scrotum for a long time and disappeared when he lay down became suddenly larger and refused to disappear. It gave him great pain and he vomited. The village practitioner who treated all acute swellings thus with good results—heated in narrow head until red hot and plunged it into the swelling causing black water to come out and then in a short time faces the pain disappeared and the patient was well but all his motions now came out from the opening which had never closed. He was well nourished and healthy looking. On the anterior surface of the scrotum just below and to the right of the root of the penis, was an opening from which semi-solid faeces were propelled intermittently. Nothing but a small amount of mucus was ever discharged from the anus. I thought it better to see if any obstruction existed internally before closing the fistula. On opening the abdomen the transverse colon was found to be the portion of bowel implicated in the hernia, while coils of bowel consisting of terminal ileum caecum ascending colon and transverse colon were adherent in the right iliac fossa. The adhesions could not be undone so the appendix having been removed an anastomosis was made between the entering loop of colon which was thus and atrophic. Following this operation faeces passed both by the fistula and by the anus. Twelve days later, on the day before the fistula was to be closed the temperature which had never been above normal rose suddenly to 103° and relapsing fever developed—not an unusual complication in the demic conditions the blood was crowded with large spirochaetes but they rapidly fell as did the temperature, after intravenous injection of neo-harsivan.

Under spinal anaesthesia the inguinal canal was opened and the bowel freed from adhesions to the peritoneal sac which was very thick, the fistula was excised and the bowel closed and returned to the abdomen. The sac being dealt with the inguinal canal was obliterated after excising the testicle and cord connection for repair being unfavourable. No further complications occurred and the patient was discharged with the bowels acting by the proper route.

As an emergency procedure with the facilities available the indigenous operation was undoubtedly excellent and probably saved the man's life.

QUINTIN STEWART FRCS,  
West African Medical Service

## Reports of Societies.

## PEDIATRICS

THE provincial meeting of the Section for the Study of Disease in Children of the Royal Society of Medicine took place at Cambridge on June 20th. By kind permission of Professor Hopkins the meeting was held in the Sir William Dunn Laboratory of Biochemistry, the chair was taken by the President, Dr H. C. CAMERON.

## Bone Formation and Rickets

A discussion on the biochemistry of bone formation and the application of this to the pathology of rickets was opened by Dr H. D. KAY, who briefly stated and criticized the various theories of the biochemical mechanism of the deposition of bone in normal animals which have been advanced by Pfander, Pauli and Sance, Freudenberg and Georgi, and particularly by Robinson and his collaborators. The central discoveries on which new ideas of the mechanism of bone formation depended were (1) that the cells of ossifying cartilage, and to a less extent those of full-grown bone, contained a powerful phosphoric esterase which decomposed most phosphoric esters readily, and (2) that there was a phosphoric ester present in blood upon which this enzyme acted, resulting in the liberation of ossification. Tertiary calcium phosphate (or possibly some compound of even greater lability) was laid down because of the local increase in the concentration of  $PO_4^{3-}$  ions brought about by the enzyme led to the solubility product

of  $Ca_3(PO_4)_2$  (or that of the more basic compound) being exceeded. The evidence on which this modern view rested was critically examined, and it was found to explain many of the facts. Rickets, however, was not necessarily associated with a shortage either in the enzyme activity of the bone, or in the amount of phosphoric ester in the blood, which was hydrolysable by the bone enzyme. Dr H. W. C. VINES suggested that in the light of Dr Robison's discovery of a phosphoric ester in ossifying cartilage, the deposition of calcium salts might be carried out according to the equations—

The double salt could be prepared by the neutralization of a solution of  $CaH_2(PO_4)_2$  by  $NaHCO_3$ . Phosphoric acid or dried calcium phosphate dissolved this salt molecularly with the formation of  $CaHPO_4$ . Taking the view that the  $Ca$  and  $P$  equilibrium of the plasma was directly dependent upon the skeletal  $Ca$  salts through the agency of  $CaHPO_4$ , it was shown that buffered protein solutions to which solid  $CaHPO_4$  was added in certain concentrations came into an equilibrium, in which the percentage  $Ca$  content was about 12 mg, and the  $PO_4$  10 mg, the pH being constant at pH 7.4. From this a graph was built up indicating the probable conditions in the plasma. It was shown that a very slight decrease in the plasma  $PO_4$  concentration would cause a fall in  $Ca$  to below 7.5 mg per cent. This would be compatible with tetanic rickets with low  $Ca$  and normal phosphorus. A further decrease in  $PO_4$  to 50 per cent of the normal value would lead to a  $Ca$  value of 9 mg per cent, indicating perhaps a rachitis with normal calcium and low phosphorus. Any further decrease in  $P_2O_5$  would lead to a lowering of  $Ca$ . From these experiments Dr Vines suggested that rickets might be associated primarily with an error in phosphorus metabolism, and that the calcium metabolism was affected secondarily. A discussion followed in which many speakers took part, and in which the decrease of the grosser forms of rickets during the last few years was emphasized, and the great variety of satisfactory methods of cure was illustrated.

Pulmonary Lesions due to the *Pneumococcus*

Dr J. F. GASKELL described certain experiments on which he had been engaged in an endeavour to elucidate the origin and relationships of the various forms of pulmonary lesions produced by the pneumococcus. Rabbits were used for the experiments, and he claimed that a close parallel existed between the lesions obtained and the various forms met with in children. All experiments had been made with a single strain of pneumococcus type I, which had been obtained from a fatal human case. The virulence of the strain was varied at will, and could be controlled and measured with sufficient accuracy by the minimal lethal dose to mice of saline dilutions of the way being expressed as the titre. With low titres no lesions were obtained in the lung, with titres between 3 and 4 either central round the main bronchus or more diffuse. With titres between 4 and 5 the lesions were larger and became lobular in type, with titres between 5 and 6 either lobular consolidation was produced or the lung lesions, though diffuse, were incomplete, and were accompanied by double pleurisy with much purulent effusion, and often also by pericarditis. To produce the lobular lesion the dose must be small. With titres of 6 and over a septicaemic condition was produced, with intense invasion of the blood stream and characteristic sero-haemorrhagic effusion in all lobes, very mild, a positive blood culture could not be obtained from the heart's blood in the first three days. Evidence was given that with the lower titres the condition was a bacteraemia rather than a septicaemia, and the theory was advanced that the organisms present in the blood were always within the leucocytes and not free. Dr Gaskell suggested that the size of the lung was of importance in the production of the lobular lesion, and that the larger

lung of adults gave a longer period for the defensive mechanisms to concentrate, and thus prevent the involvement of the pleura, while in children the periphery of the lung was reached by the spreading infection much more rapidly, and thus empyema was common and lobular pneumonia comparatively rare.

After the meeting a dinner was held in Christ's College, by kind permission of the Master and Fellows.

### TROPICAL MEDICINE

The annual general meeting of the Royal Society of Tropical Medicine and Hygiene was held at 11, Chandos Street, Cavendish Square, on June 18th. The retiring President, Surgeon Rear-Admiral Sir Percy Bassett-Smith, handed over the badge of office to the newly elected President, Dr ANDREW BALFOUR, who, in taking the chair, reviewed the activities and growth of the society during the two years' presidency of Sir Percy Bassett-Smith. The Chalmers Memorial Gold Medal, which is given biennially to persons under 45 years of age for "researches of outstanding merit contributing to our knowledge of tropical medicine and hygiene," was presented by the new President to Professor Warrington Yorke of the Liverpool School of Tropical Medicine, in recognition of his work on trypanosomiasis, malaria, and many other subjects.

#### Observations on Malaria during Treatment of General Paralysis

Professor WARRINGTON YORKE read a paper on "Further observations on malaria made during treatment of general paralysis," a previous communication on the same subject having been made by him in conjunction with Dr J. W. Scott Macfie last year. They had noted that induced malaria, whether as a result of direct inoculation of the blood of an infected patient or the bites of infected mosquitos, was remarkably susceptible to the action of quinine in a dosage of 30 grains on three consecutive days. It was further discovered that quinine has no true prophylactic action, for in the case of patients bitten by infected mosquitos daily doses of 10 grains of quinine, administered for five days before, on the day of, and for seven days after, the infecting bite of the mosquito did not prevent the onset of typical malaria. Similarly, 30 grains given on the day of the bite and on each of the two succeeding days did not prevent malaria. From these results it was evident that quinine, though very efficacious for the primary attack of malaria when parasites appeared in the blood, had no action on the sporozoites injected by the mosquitos. The communication made by Professor Yorke dealt with the subsequent history of the cases reported upon last year. Of the cases, which numbered over a hundred, of malaria induced by the inoculation of virulent blood and treated by the three-day course of quinine from one and a half to two and a half years ago, the number of relapses had remained at 2 per cent. The inoculation of the strain from man to man during three years, involving more than forty passages, had not produced an increase in virulence or any morphological variation in the parasite itself. Turning to the infections induced by the bites of mosquitos and treated like the series just mentioned, the more prolonged observations showed that 21 of the 37 patients relapsed. Of these 2 relapsed in the first month, 2 in the second, 1 in the third, and the rest from the fourth to the eleventh months. The late development of these relapses was in marked contrast to the experience of the war, when the vast majority of relapses occurred within one to one and a half months of cessation of treatment. Of the 21 relapses, in the majority of cases fever disappeared either spontaneously or as a result of a second short course of quinine. These results were very different from those obtained during the war. It did not appear that the amount of quinine or the manner of its administration, the period of the year when infection or treatment occurred, or the strain of parasite, could explain this outstanding difference. The only factor which could reasonably account for it was the individuality of the patient. This factor appeared to be the one which determined whether a relapse would occur and if so when.

On the subject of the mechanism of the action of quinine Professor Yorke could see no reason to alter the opinion expressed in the communication made last year. Quinine destroyed large numbers of the malarial parasite, but had no bodies of which acted as an antigen to stimulate the production of antibodies which, if present in sufficient amount, brought about a sterilization of the infective and the cure of the patient. As to the immediate action of quinine in destroying parasites, some evidence had been obtained that the drug, acted indirectly, certain bodies co-operating with the quinine in producing a substance directly toxic to the parasite. The use of large doses of prolonged courses of quinine was not advocated. On the other hand, the best method of treating malaria was to deal with the attack with a few moderate-sized doses at an early development, if relapses occurred the treatment should be repeated, the general health should be maintained by diet and the avoidance of exhaustion, for relapse was directly related to the reaction of the patient himself and his capacity to develop immune body.

### CHLOROFORM ANAESTHESIA

A meeting of the Anaesthetic Section of the Royal Society of Medicine was held in the University Buildings at Manchester on June 27th.

Dr H. P. FAIRHURST (Glasgow) opened a discussion on chloroform anaesthesia. At a time when chloroform was being subjected to criticism as an anaesthetic, even to the extent of protesting altogether against its use, he thought it proper that its legitimate uses should be discussed since a considerable amount of space in textbooks was devoted to the teaching of its exhibition as an anaesthetic. The fact that people talked of an ideal anaesthetic seemed to indicate that no ideal anaesthetic had as yet been discovered. On the other hand, Professor Hobday considered chloroform the ideal anaesthetic for animals. Ether was the most formidable rival of chloroform, and it certainly had its proper place as an anaesthetic, though it was not supreme. It was productive of fatigue, its stimulative action on the circulation left the patient in a condition of reaction at a moment when stimulation was most needed, and the subsequent fall of blood pressure was the cause of many post-operative fatalities. Dr Fairhurst thought too much emphasis was laid on the condition of the patient during operation, and the after-effects were ignored. Statistics were misleading, as they included many personal factors, such as variations in skill of different anaesthetists and variations in the condition of the patients prior to operation. Chloroform should not be the choice of the occasional anaesthetist, but the expert would not have more fatalities with it than with ether. Desirable surgical conditions were more easily reached with chloroform than with ether, while in the post-anaesthetic stage the blood pressure tended to rise and would respond to stimulation. At the time of operation there was less tendency to bleeding, and afterwards the chances of lung complication were fewer. As offsets to these advantages there was certainly the danger of acidosis and chloroform syncope. It was usual to classify syncope as of two kinds—sudden and gradual. There was, however, no vital distinction between the two. They were of the same nature, differing only in rapidity of onset. In the sudden variety the time available for remedial measures was less. It was rarely necessary to do more than control the circulation by putting the patient in the Trendelenburg position if the condition were recognized at the onset. Lary considered ventricular fibrillation the result of light chloroform anaesthesia rather than overdosage. The suprarenal glands were stimulated, and the result was fibrillation. As the result of clinical experience the speaker did not agree with the overdosage theory, whereas the alternative theory of vagus inhibition appealed to him. He said he practised light dosage with a Veinon-Harcourt apparatus up to 3 or 3½ per cent of vapour strength, the bottle being immersed in hot water to increase the percentage and keep it uniform. Atropine gr. 1/100 was given to adults, and in smaller doses to children. In the later stages of anaesthesia deficient oxygenation was combated by oxygen inhalations, and in deep abdominal cases was given through out. Sepsis in the abdominal cavity ruled out chloroform.

In conclusion, he quoted Willet, who stated that if he had to be operated upon and the anaesthetist was unknown to him he would choose chloroform for the anaesthetic, but if he had a warning, and could choose his anaesthetist he would prefer chloroform.

Dr J. BLOMFIELD (London) said it was difficult to criticize a paper which was so eminently rational, and he only differed from the opener on one point. There were certainly two kinds of chloroform syncope, and from clinical experience he concluded that there were deaths due to overdosage and deaths without overdosage. He had seen a man die in the early stages of chloroform anaesthesia, the administration being conducted by a competent anaesthetist, the corneal reflex still brisk, there being no evidence of overdosage, no high concentration of the drug, no deep anaesthesia, the patient sitting up in his struggles, when he suddenly fell back and died.

Dr S. R. WILSON (Manchester) agreed with the opener on many points, but he disputed Professor Hobday's dictum regarding chloroform as the ideal anaesthetic for animals. It was the regular thing for two out of every ten or twelve dogs anaesthetized with chloroform to die, whereas he himself had not lost a single dog in the past five years when giving ether. Veterinary anaesthesia was in the same position to-day as that of human anaesthesia twenty years ago. He agreed with Dr Blomfield that there were two types of chloroform syncope. If vagus control had any importance, why give atropine as a routine measure?

Dr W. J. McCANN (Birmingham) believed that a C.E. mixture varying in proportions with the type of case was the nearest approach to the ideal anaesthetic. When giving chloroform sufficient was not done to ward off its dangers. The patient should have preliminary preparation with brandy, strychnine, atropine, digitaline, and pituitum. Ether was given for too long at a time, and 17 hours deep ether anaesthesia was enough for anyone. In certain operations a mixture was essential—for example, in operations on children on the eye in brain, mastoid, Gasserian ganglion, and lung operations.

Dr G. R. PHILLIPS (London) called attention to the construction of the Vernon Harcourt inhaler in which a special apparatus was provided to increase concentration up to 41 per cent, without heat. The percentage of chloroform used was uncertain when heat was used. Dr C. P. THOMAS (Birmingham) advocated the routine lowering of the head a few inches as a precaution against heart failure when using chloroform, especially in gynaecological cases.

Dr ALEXANDER WILSON (Manchester) said that he had met with two patients who died on the table before any anaesthetic had been administered. The patients died from circulatory failure precisely similar to that which occurred after severe haemorrhage. The symptoms were pillor and dilatation of the pupil, with convulsions in some cases. Artificial respiration should be commenced at once, and the head of the table lowered. Overdose occurred in two conditions. In one there was violent struggling, with consequent deep inhalations and subsequent overdose. In the other the patient was gradually over-osed, even with small amounts, as the result of respiratory obstruction. In the first, death was due to cardiac paralysis, resulting from over-excitation, and not really to chloroform. Again, from over-excitation, so common in the past, might be a contributory cause.

Dr FETTERSTONE (Birmingham) said that he must have clear reasons for so doing before giving chloroform, for once the drug had been absorbed it was well-nigh impossible to get it out of the system quickly. Light anaesthesia at the beginning of operation was dangerous, and there was also a danger of collapse later, in children, when they had been returned to bed. Moreover, with chloroform there was a fall in the systolic pressure during administration, accompanied by a rise in the diastolic pressure. Thus the weak pulse was hampered, not only by a falling output of the heart, but also by increased peripheral resistance. Nervous patients should never be given chloroform, for fear of collapse.

On the conclusion of the discussion, a demonstration was given in the physiological laboratory by Drs S. R.

WILSON and B. McSWINEY of the effects of adrenalectomy injections during chloroform and ether anaesthesia on a dog. An exhibition was also arranged of physiological methods of investigating acidosis, and a new anaesthetic apparatus was also on view.

## TUBAL PREGNANCY

At the last meeting of the North of England Obstetrical and Gynaecological Society, held at Leeds, with Dr J. L. GYMILL, President, in the chair, Dr E. O. CROFT (Leeds) recorded several cases of tubal pregnancy recently operated on by him presenting somewhat unusual symptoms.

1 The first patient a married woman aged 39 whose only child was born ten years ago had menstruated regularly until June, 1924. This period was prolonged to seven days and on the seventh day she had a sudden violent pain in the left groin passing through to the rectum. Colicky in nature which lasted twelve hours. Two shorter similar attacks of pain followed at intervals of six hours and vaginal bleeding continued for a week. She then had, during the following six months varying slight attacks of pain, with menstrual periods regular though increased in amount. She was admitted to hospital on January 17th 1925 when there was rigidity in the left lower quadrant of the abdomen and on vaginal examination a small swelling in the left tubo-ovarian region was felt. At operation a small dark round mass was discovered in the tube and on handling this the tube broke across just proximal to the side of this lump. Beyond it the tube appeared normal. The entire tube was excised. The points of intratubal bleeding and mole formation remaining for six months with return of menstruation and the small size of the mole contained in a small portion of the tube the rest of which was normal. The length of time the mole had been retained must have accounted for the lack of microscopic evidence of villi on examination of it.

2 The second patient was aged 42 had four children (the youngest born five years previously) and had had left salpingo-oophorectomy for tubo-ovarian abscess fourteen years previously. The points of interest in this case in addition to the previous operation were the absence of amenorrhoea and the large amount of evidence of old inflammatory disease around the tubal mole and there was no history of any acute symptoms.

3 This case was that of a married woman aged 29 who had had one child and one abortion. She was admitted to hospital in June 1924. She had slight loss and slight pain for a day or two and then three days before admission a severe flooding which subsided. On the day of admission she had severe pain and was very blanched and suffering severely from shock. At operation the right tube was much enlarged and there was a large quantity of free blood in the peritoneal cavity. The tube was removed and later after hardening was opened and found to contain a perfect ovum with embryo in its amniotic cavity. The points of interest were the absence of amenorrhoea, no mole formation (ovum intact), and profuse haemorrhage from the open end of the tube.

4 This patient aged 31 was married and had two children the second born six years previously. She began to lose on January 18th 1925 the date her normal period was due but she only had slight aching pain in the abdomen never on acute attack. Vaginal examination revealed the uterus displaced forwards by a tender swelling in the pouch of Douglas. At operation much dark tarry blood was found in the peritoneum with the right tube ruptured and containing much clot. Haemorrhage there was no amenorrhoea but two months continuous loss and an absence of any acute attack of pain in spite of a severe rupture of the tube and intraperitoneal haemorrhage. The interest of this case was that after a series of six abortions none of which went beyond six weeks the patient had a tubal pregnancy and the later history resembled more that described in textbooks seven weeks amenorrhoea with sudden attack of pain and slight loss followed by severe pain and free bleeding.

5 This patient had two years sterility following marriage and then on July 16th 1924 a month after a normal period had severe pain in the left lower abdomen and a week later slight bleeding which continued for three weeks to the date of admission. For three days before admission she had severe pain and at the operation a large amount of intraperitoneal haemorrhage was found with a mole still present in the left tube. The points of interest were two years sterility and pain at the date of the expected period but no show until a week later.

In recording these cases Dr Croft drew attention to the unusual points, indicating how the usually recognized symptoms and signs were only exceptionally present in any one case, and endeavoured to show that early symptoms, if seriously noted, would more often lead to earlier treatment before an acute catastrophe took place.

*Treatment of Incision of the Uterus*  
Mr W. W. KING (Sheffield) read notes of a case of incision of the uterus replaced by a new form of Aveling repositors. The case was of interest because of the slight

trauma which apparently began the process, and the case with which the inverted uterus was replaced by his modification of Aveling's repositor three weeks after the accident.

The patient, aged 27, was delivered spontaneously of her first child on March 1st, 1925. A slightly abnormal amount of haemorrhage during the second stage caused her medical attendant to put his hand into the vagina for the purpose of removing the placenta from the uterus. The placenta was, however, mainly in the vagina and came away without any difficulty. Serious collapse and vomiting followed immediately but no further haemorrhage. Inversion was thought of but the absence of haemorrhage and an external tumour were taken by him to negative the diagnosis. The shock passed off, and the puerperium was afebrile and on the eighteenth day a routine pelvic examination was made. This disclosed a rounded tumour in the vagina which was recognized as an inversion. Mr. King saw her the same day when she looked and felt perfectly well. The inverted uterus was the size of a cricket ball in the vagina. She was admitted to hospital and after a few days' treatment with glycerin the modified Aveling's repositor was inserted and the uterus was completely reinserted in six hours, with very little pain or discomfort. Recovery was uninterrupted.

The instrument, as modified by Mr. King, made it possible to get the point from which traction was made as close to the vulva as possible, and so diminish the liability to lateral displacement, secondly to supply a ready means of adapting the shape to that of the vagina, and thirdly, a gauge is provided by which the process of reinsertion could be noted without removing the apparatus.

The stem was of copper and could be bent to fit the curve of the vagina and so transmit pressure in the correct axis. Before fitting the apparatus a small piece of strapping placed on the stem should indicate the position the plate would occupy when the fundus had been reinserted to a point at or about the cervix. The plate from which traction was made was rectangular measuring 6 by 3 cm. and could be fixed at any position on the stem by means of a set screw. The corners of the plate were drilled to take the ordinary circular elastic bands supplied in stations. When these bands were looped into the holes and attached to a suitable belt and extended by about 2.5 cm. the right amount of pressure was produced. Attached at first half an inch from the vulva and readjusted as reinsertion took place, the prearranged point indicated above would be reached. The cup used was of the ordinary type till the fundus had been replaced to the level of the cervix and then the instrument was withdrawn and the cup replaced by a smaller cylindrical one which could easily pass through the cervix. After reinsertion this cup could be withdrawn with great ease and no pain.

The President congratulated Mr. King on the instrument and its successful use. Dr. Croft thought the original Aveling repositor was conical at the lower end, and so its removal was easy.

#### *Puerperal General Peritonitis*

Dr. CARLTON OLDFIELD (Leeds) read notes of two cases of puerperal general peritonitis. At the outset he referred to a short paper, contributed by himself to the Society two years previously, on twelve cases operated on, with seven recoveries. His main reason for returning to the subject was that the statistics of the recent investigation of puerperal infections proved two things that general peritonitis was very common, and that the treatment of it was by no means successful.

The first patient had a spontaneous delivery on January 30th, 1925, the only interference being rupture of the membranes by the midwife when they were bulging at the vulva. On the sixth day after delivery—sixteen hours after the onset of severe pain—she was admitted into the Leeds Infirmary with temperature 99.8° F., pulse 108 and the abdomen rigid and tender, not moving on respiration. Laparotomy allowed large quantities of yellowish foul-smelling liquid to escape from the peritoneal cavity. The appendix and right tube were normal, the left tube red and inflamed. Left salpingectomy was performed with drainage of the abdomen. Examination of this tube showed it acutely inflamed, no organisms were grown from the fluid removed. The patient made a good recovery.

The second patient was 31 years old and had four children. She had a profuse purulent vaginal discharge during pregnancy, normal labour on December 29th, 1924. One hour after delivery the temperature was 103° F. and pulse 120. Pyrexia persisted with rigors on the second, fourth, fifth and sixth days after delivery. On January 4th, 1925, the temperature was 104° F., pulse 135, she had severe abdominal pains, diarrhoea and occasional vomiting, and the abdomen was distended. She was operated on the next day, and a large quantity of sero-purulent fluid evacuated. The left tube which was swollen and congested was removed and drainage tubes put in the pelvis. She died on January 9th of general peritonitis. Streptococci were grown from the fluid.

Dr. Oldfield thought it desirable that in cases of puerperal infection a sharp lookout should be kept for

evidence of general peritonitis, and the abdomen should be opened as soon as the condition had been diagnosed. His experience of fourteen cases (with eight recoveries) appeared to show that the death rate from puerperal peritonitis could be considerably reduced by operative treatment on the lines adopted by surgeons in treating general peritonitis.

#### *Breech Presentation and Ectopic Pregnancy*

Dr. GORDON FITZGERALD (Manchester) read notes of a case in which a breech presentation was complicated by an extrauterine pregnancy.

The patient, a 4 para, aged 32, was admitted to hospital in labour the breech presenting. Previous labour had been without difficulty and so none was anticipated here. During the second stage there was considerable delay, and on examination a mass was found in front of the breech which resembled a cervical lip, supported by the presenting part. The swelling was soft and bluish and the efforts made to push it up were unsuccessful. After some further delay the mass ruptured and there was much haemorrhage, and then the labour was terminated fairly quickly. The uterus contracted well following a slight further haemorrhage. Two days later, after a recurrence of haemorrhage, Dr. FitzGerald examined her and was surprised to find the examining finger pass more easily through an opening in the posterior fornix than up towards the cervix. Under an anaesthetic a cavity filled with blood clot lying in the left broad ligament was found. From the cavity recent and old blood clot was removed and also a small embryo about an inch in length. The cavity was briefly packed with gauze which was removed in twenty-four hours, and the puerperium was otherwise uneventful.

No indication was obtained from the patient's history as to when the extrauterine pregnancy ruptured through, or was aborted from, the tube. Accepting the view that ovulation ceases during pregnancy, this (two months' embryo) must have remained about eight lunar months unabsorbed.

#### *Uterine and Ovarian Tumours*

Mr. W. GOUGH (Leeds) described two cases of sarcomas of the uterus.

The first patient, aged 66, had her last pregnancy twenty-three years ago, menopause ten years ago. There was a history of three months' vaginal haemorrhage but no pain. Exploration with a curette produced rounded compressed nodules, the colour of milk chocolate, which on examination showed sarcoma of a mixed cell type. Vaginal hysterectomy was done and the uterus examined later had the pedicle of the polypoid growth still present on the posterior wall half an inch from the fundus.

The second patient, aged 59, had one child thirty years ago and ever since the menopause eight years ago had suffered from discharge with occasional bleeding. Examination revealed a hard rounded central tumour extending to two inches above the umbilicus and a large polypus with sloughy surface filled the vagina. At operation the polypus broke into fragments with suspicious ease and a large quantity of greyish stringy growth was removed from the uterine cavity. Microscopical examination showed a rounded cell sarcoma. Abdominal parasthysterectomy was performed. On opening the specimen the fundus was found to contain a fibroid as large as a tangerine orange below this was a large cavity with foul sloughy nodular walls from which the growth had been excavated at the first operation.

The second case might have been one of so-called sarcomatous degeneration of a fibroid, but Mr. Gough held that this did not occur, for he had never seen a section showing definitely this change.

Dr. CARLTON OLDFIELD showed a specimen of a growth about the size of a walnut projecting from the anterior wall of the cervix, removed by Wertheim's operation, which, on pathological examination, showed an adenoma with no definite evidence of malignancy. He had taught for many years that cancer of the cervix could be diagnosed, practically always, by the finger or a Volkman's spoon. He considered it unnecessary, and often harmful, to cut away a piece for microscopic examination before operation, but showed this specimen as an instance in which a mistake in diagnosis would have been prevented by a microscopic examination.

Dr. Croft showed a specimen of fibrocystic tumour of the ovary. The major part of the tumour consisted of dense, fibrous tissue in which a few strands of involuntary muscle fibres appeared. Several cysts were present, one the size of a fist and the others from one half to two inches in diameter. The walls of two small cysts were calcified. This was no doubt a fibromyoma of the ovary, showing the unusual development of cysts.

## Reviews.

### ALLBUTT'S SUMMARY VIEW OF ARTERIO-SCLEROSIS

THE LATE SIR CLIFFORD ALLBUTT'S recently published *Arterio-sclerosis: A Summary View* has its saddening associations. Though to the last mentally as young and progressive as ever, he had been conscious of physical failure, and so was almost feverishly anxious to finish what he felt would be his last utterance. He did, indeed, succeed in completing a work which contains references to papers by others published as recently as January last, but he was never to see any of the proofs of this much expanded lecture to a post-graduate class in Cambridge. It was characteristic that, not content with his classical two volumes on *Diseases of the Livers, including Angina Pectoris* (1915), he continued to work, to collect fresh observations, and keep up with the literature on the subject of hypertension with which his name must long be intimately associated. This essay, divided for convenience into six chapters and provided with an excellent index, is written in the attractive style so characteristic of the scholar-physician whose modesty perhaps somewhat hid his real greatness, so that time will probably even heighten our appreciation of this master mind.

At the outset the reader's critical sense is whetted by the probing of the meanings of the abstract phrases so glibly on our lips, which appear to give more satisfaction than their unaltered interpretation really justifies. "Intestinal toxins" is criticized as a most pernicious catchword, for, as someone said of another writer, "we are guessing in the dark about a guess in the dark." Arguments are later brought forward against the popular view that arterio-sclerosis is due to poisons manufactured in the intestine, on the grounds, among others, that most of these bodies are depressor and asphyxiating rather than pressor, and the production of hypertension is referred to "a wisp of metabolism, possibly in the liver." But later he adds that if he were to suspect intestinal toxins as a cause he would give large doses of charcoal and might try kaolin.

The discussion of morbid anatomy carries the story pleasantly back to the far-off battle, some fifty years ago, when he had the opportunity of comparing the microscopic sections of George Johnson on the one hand, and of Gull and Sutton—or, as his friend Dr. W. H. Dickinson used to call them, "the allies"—on the other hand, the appearance of alleged hypertrophy of the muscular media he regards as one of increased tone only, under the influence of some cigot-like poison. After a generous reference to Dr. H. Batty Shan's monograph on *Hypertension and Hypertension*, the first of these two conditions is defined as a disease independent of the kidneys, with its own characters, of which high arterial pressures, systolic and diastolic, seem to be the chief, while hypertension is a general term for incidental high blood pressures. That some normal individuals have a systolic pressure of 160 to 170 mm. Hg he does not believe, though he cannot deny this statement any more than that in some "normal persons" the bowels act only once or twice a week. Insistence is laid on the instability of abnormal pressures, whether high or low, and on the probable occurrence in the subjects of intermittent phases of indisposition, recurrent headache, "suppressed gout," or "biliousness," of periods of high blood pressure as part of some obscure metabolic perversion or transient toxæmia, investigation of which, though they are perhaps difficult to catch, may throw light on the causes of hypertension.

In the chapter attractively entitled "Clinics" Sir Clifford Allbutt's long experience sounds the warning that, in spite of the general and more optimistic opinion, dyspnoea, however slight, means that the hypertensive patient whether renal or non-renal and even though blissfully unconscious of illness, has entered, not upon the first, but upon the last stage of his malady. He points out that uræmia occurs in cases of hypertension without any renal change, and is emphatic that severe uræmia even with neuro-retinitis may occur in cardiac disease in which the

kidneys show nothing more than congestion. But the outlook is widely different in the renal and the non-renal cases, for when the kidneys are capable of recovery the uræmia may be transient, and in the majority of such instances recovery follows a first or even a second attack. The slight and often transient paralyses or aphasias the "slight strokes" often by "sanguine pathologists" ascribed to passing spasm of the cerebral vessels, are regarded as of the worst urgency and probably due to small haemorrhages. Sir Clifford reiterates his opinion that in the majority of patients with angina pectoris the blood pressure is not raised, and says that in practice the cases with high pressure are more amenable than the ordinary run to treatment or to cure, but there is not any reference to the surgical treatment of angina, on which Professor K. F. Wackbach lectured at the Royal College of Physicians last year when Sir Clifford spoke so finely and impressively (*vide BRITISH MEDICAL JOURNAL*, 1924, 1, p. 828).

The chapter on treatment is valuable, especially for its wise and wide survey. In speaking of the insidious onset and the suggestion that everyone should be examined and have the blood pressure estimated every five years, the comment follows that "this rule would indeed set up an epidemic of sidgets." The doctrine not to treat high blood pressure as such on the ground that it is merely a symptom, and that it is "compensatory," and so would be an unscientific therapeutic procedure, meets with scant sympathy at his hands. The action of vasodilators is transient and gives but momentary relief, too strict a diet is inadvisable, and, like vasodilators, vasectomy is disappointing though useful at times. For iodides, which he usually gives in 1-grain doses twice or thrice daily in atherosclerosis with or without high pressure, no enthusiasm is expressed, but spirit treatment under watchful guidance is admitted to be very helpful though the fish air, change of scene, and attendant freedom from worry are far more important than "the water chemicals." The recent use of diathermy is recorded and the sphere of utility of endocrine preparations philosophically considered.

In conclusion, short as is the "Summary View" it is a welcome and useful record of the mature and wise final expression of the great Regius Professor's long experience, and will therefore appeal to the profession of which he was eminently the recognized leader.

HUMPHRY ROLLSTON

### THE CELL IN DEVELOPMENT AND INHERITANCE

THE title of the first edition (1896) of the work by Professor Wilson of the chair of biology at Columbia University, U.S.A., was *The Cell in Development and Inheritance*, and as such for the next ten years we accounted that work one of the most valuable of the monographs of the Columbia University Biological Series. But much of the water of life has flowed under the morphological bridges within the last thirty years.

The first edition had 377 pages and 142 illustrations, as compared with the 1232 pages and 529 illustrations of the splendid work before us.

In the new edition the old title is slightly altered, but no title of reasonable length could describe the contents of this storehouse of facts and theories, for here are treated in the fullest manner possible all of the following. The general morphology of the cell, cell division, reproduction and cell life, gametes, fertilization and parthenogenesis, meiosis, sexuality in lower organisms, cell chemistry and cell physiology, chromosomes and sex, heredity and the chromosomes, growth and cell development, and development and heredity.

We are left in doubt which is the more worthy of admiration—the complexity, resource and infinite variety of Nature or the vast patience of the author of this treatise. We are particularly glad to find that this book so up to date in every respect, yet opens with a sympathetic recognition of the place of the cell theory of Schleiden and

*The Cell in Development and Heredity* By Edmund B. Wilson. Third edition. New York: The Macmillan Company, 1925. (Med. 8vo, pp. xxxvii + 1232, 529 figures, 36s. net.)

Schwann in biological history. For there has been of late a tendency in certain quarters to belittle the importance of that generalization made under the disadvantageous conditions surrounding the study of life nearly one hundred years ago. So wholly praiseworthy is Professor Wilson's view on this subject that we must quote his opening sentences:

"Among the milestones of modern scientific progress the cell theory of Schleiden and Schwann, enunciated in 1838-39, stands forth as one of the commanding landmarks of the nineteenth century. Its importance is not to be judged by its original form, as first outlined, it was but a rude sketch, in many respects faulty and distorted. Its announcement nevertheless marked a turning point in the advance of biology, opening a new point of view for the study of living organisms and revealing the outlines of a fundamental common plan of organization that underlies their endless external diversity. The cell theory thus became a perennial source of fruitful researches, which, down to our own day, have continued to press forward into always expanding fields of discovery. Long ago it became evident that the key to every biological problem must finally be sought in the cell for every living organism is, or at some time has been, a cell."

Words as true as they are necessary.

It should not be supposed that this book is just a catalogue of facts of microscopic cell morphology, such catalogues and speculative topics is living matter a continuum, the immortality of protoplasm, syngamy, senescence and rejuvenescence, rhythm, rhythm, and many other theories of fundamental interest are discussed. The bibliography alone is extremely valuable, and there is a welcome glossary of terms. There are two indexes—one of authors, the other of subjects. The figures throughout are exceedingly clear.

#### NERVOUS DISEASES

In the preparation of the second edition of his textbook of nervous diseases<sup>1</sup> Professor HANS CURSCHMANN has had the assistance, as co-editor, of Professor FRANZ KRAEHLER of Berlin, during the fifteen years which have elapsed since the first edition appeared three of the original contributors have died—Professors HANS STEINER, MAX ROTHMANN, and MAX LEWANDOWSKY. To the new volume there are twelve contributors, including the two editors, it contains over nine hundred pages and there are some three hundred illustrations, many of them photographs of cases, carefully chosen and exceptionally good, and constituting in themselves a very useful study. After an opening chapter by Professor KraeHLer on the general examination of cases of nervous disease, the book follows in anatomical basis, diseases of the peripheral nerves being first considered by the same writer. Professor F. K. WALTER deals with the diseases of the spinal cord and medulla oblongata, among which is included disseminated sclerosis, before the individual diseases are described full accounts are given of the anatomy and physiology and of the regional diagnosis of cord lesions. The myopathies, including dystrophies, myotonia and myasthenia, are discussed by Professor CURSCHMANN. Professors HUGO LIEPMANN and KRAEHLER contribute a detailed chapter on the general anatomy and physiology of the cerebrum and cerebellum, the methods of examination and localizing features of brain lesions, and an account of the different types of aphasia. Chapters follow on meningitis and hydrocephalus by Professor HUGO STAECK, on brain tumours and brain abscess by Professors LEWANDOWSKY and GEORGE SEITZ, and on cerebral syphilis by Professor R. GRUPP. Professor SEITZ deals with encephalitis and vascular lesions, with diseases of the extrapyramidal system, and with certain types of idiosyncrasy, all the accounts are thoroughly up to date and are well illustrated. An interesting section on the physiology and pathology of the vegetative nervous system, written by Dr R. GIEVING, is followed by a chapter by Dr CURSCHMANN on nervous disorders associated with the endocrine organs (exophthalmic goitre, myxoedema, tetany, acromegaly and Frolich's syndrome, and lipodystrophy). Vasomotor and trophic disorders are considered by Professor CURSCHMANN, and nervous diseases due to intoxications by Professor F. QUENSEL. Lastly, there are accounts of the orthopaedic treatment of nerve lesions by Professor H. v. BAAYER, and

of the surgery of nervous diseases by Professor FEDOR KIANSE.

This book is a comprehensive manual of nervous diseases. It contains sufficiently detailed accounts of rare diseases to be of value both to neurologists and general physicians, and it should prove an excellent book of reference for the practitioner who desires to keep in touch with modern neurology. A textbook of this standard in English, but not a mere translation, seems to be needed.

#### NOTES ON BOOKS

THE editor of the history at home and abroad of *The 21st London Field Ambulance* during the great war is to be congratulated on having produced a most readable book, which can be read with interest by those who had not the good fortune to serve with the unit whose exploits it commemorates. After preliminary training in England the unit left Ipswich at midnight on 1 February 20th-21st, 1916, touched at Southampton, left there for Le Havre on the evening of 1 February 21st, and thence proceeded to the village of Atraines, there it joined the 56th Division, with which it served for the remainder of the war. It received its first real glimpse of heavy fighting in the Somme area, and, after doing duty at the capture of Combles, was moved to the La Bassée-Laentue area, where fighting was of a less exciting nature. Here it stayed until March, 1917, when it moved towards Arras for the first Arras battle. Next it visited St. Omer and shared in the third battle of Ypres, after which it went to Bapume and wintered at Aubigny. In March, 1918, the unit went through the famous German offensive against Cambrai and from that time to the close of hostilities took part round Arras in the many engagements which preceded the German retirement, finishing up at Query le Petit on the eve of the signing of the armistice. After further moves later to Mons and Jemappes the unit was sent home by way of Antwerp and demobilized at the Crystal Palace. Its roll of honour comprised twenty-four names, and its honours and awards numbered forty-two, including four mentions in dispatches. The book is well printed and illustrated with photographs and sketches. A foreword by Lieut. Colonel C. S. BRENNER, D.S.O., who commanded the unit from its foundation until after the armistice, explains the reason for the delay in its appearance. Copies may be obtained from H. L. Chase, "Kingsley," Merstham, Surrey.

Rice is, it has been stated, the staple food of more than half the population of the world. If for that or for any other reason a reader of the *BRITISH MEDICAL JOURNAL* should take it into his head to cultivate rice he will learn to what countries he may go and all about its production from a little book<sup>2</sup> by Mr C. E. DOUGLAS. It appears to be the first work published on the subject, and deals with it in every aspect—historical, ceremonial, botanical, physical, with the details of its cultivation, with its relation to soil, to climate, to its food value, and, finally, with exactly the right way to cook rice and prepare a rice pudding—which is undoubtedly useful knowledge if duly applied. The little book is one of a long and excellent series issued by the same publishers on common commodities and industries.

#### PREPARATIONS AND APPLIANCES

##### A Self-retaining Anal Speculum

MR. HAROLD BURROWS, OBE, F.R.C.S. (Southsea) informs us that Messrs Arnold and Sons (John Bell and Croyden, Ltd.) 50-52, Wigmors Street, W.1, have recently made for him a small self-retaining speculum, which is especially useful for the injection treatment of piles. On the end of the speculum is a bulb which renders it self-retaining, so that the operator has both his hands free.

##### Using Testing by Diabetic Patients

DR A. CLARKE BEGG (Swansea), having found the advantage of diabetic patients examining their own urine regularly, has devised, and Messrs Allen and Hanbury, Ltd. 48 Wigmors Street W.1 have made a small outfit for their use. It is packed in a wooden case which contains Fehling's solution No. 1 and 2, the (dilute) solution of non-perchloride a spirit lamp, half a dozen test tubes, a notebook to record daily results, and full directions for the test. Dr. Begg recommends Fehling's instead of Benedict's test as all medical men are familiar with the former and can better assist the patient if he gets into difficulties. Dr. Begg thinks it essential that patients should test occasionally for diacetic acid, and should be instructed to get medical advice at once if any red coloration is shown with the iron perchloride.

<sup>1</sup>*Lehrbuch der Nervenkrankheiten*. Herausgegeben von Dr. Hans Curschmann, Ro. tock und Dr. Franz KraeHLer. Berlin. Zweite Auflage. Berlin Julius Springer. 1925. (Roy. 8vo, pp. x + 952. illustrated. G.M. 36.)

## FIRST INTERNATIONAL CONGRESS OF RADIOLOGY.

## LONDON MEETING

THE International Congress of Radiology, the opening of which was reported in our last issue (p. 32), closed on July 4th, after a very successful four days' meeting at the Central Hall, Westminster, under the general presidency of Mr C THURSTON HOLLAND, C.B.M. The British organizers had described it as a "preliminary meeting," but directly the Congress assembled a meeting of the international delegates resolved to declare it the First International Congress of Radiology, and to elect Mr Thurston Holland as its President. At a later meeting of the delegates it was resolved that the Congress should meet next in Stockholm in 1928 under the presidency of Professor GOSTA FORSSSELL. Some general principles were adopted for the guidance of future Congresses, one of which was that any country having a radiological society or societies should be entitled to send not more than five official delegates, but that only one vote should be exercisable by each country. Professor Forssell was appointed chairman, Mr Thurston Holland vice-chairman, and Dr Stanley McWhille secretary, of the international delegates' committee, pending the next meeting of delegates.

The proceedings of the Congress took place in three sections. The Section of Physics was presided over by Mr C. L. S. PHILLIPS, the Section of Electrophysics and Actinotherapy by Sir HENRY GAYLOR, and the Section of Radiology was divided into two parts—one for the discussion of radio-diagnoses and the other for the discussion of treatment by radium and x-rays. Dr A. E. BARCLAY presided over the first, and Dr N. S. FRANK over the second. These two halves of a section each carried out a very full and well co-ordinated programme, the one beginning with radiological diagnosis of bone conditions, and passing on to the gall bladder, the alimentary tract, the thorax, and the skull, while the other devoted three sessions to radium therapy and three to x-ray therapy. The number of papers read was 150. It is possible only to note some of the outstanding communications.

## RADIOLOGICAL DIAGNOSIS

*The Position and Form of the Stomach*

Dr R. O. MOORE (Oakland, California) brought forward the results of an x-ray study of the living anatomy of the stomach, liver, and colon in 1,000 healthy adults. He showed that in 75 per cent of the male subjects the lowest part of the greater curvature was below the interiliac line, and that this position was most frequently in a zone from 2½ to 5 cm below that line. In the female subjects the lowest part was below the line in 88 per cent of the cases examined, and in 43 per cent was more than 5 cm below the line. In 12 per cent of the males and in 30 per cent of the females the lesser curvature also was below the interiliac line. The pylorus in both sexes was most often found well below the transpyloric plane. All these were thoroughly normal and healthy subjects. He held that the use of the term "gastroptosis," like "coloptosis" also, was seldom justifiable—the form, position, and relations of the abdominal viscera differed so widely among normal individuals.

Dr I. S. HINSCHE (New York) complained that his compatriot had made no mention of the great work on this subject done by Mills of St. Louis, who had shown, after many years of very careful examination, that there was a definite relationship between visceral form and bodily habitus. Dr Moore said that he fully appreciated Mills's work, though he did not think that the position of the stomach could be so exactly guided according to changes in the bodily habitus as Mills had described. With regard to the need of this work, it was enough to point out that both in England and America there were thousands of physicians who regarded a "fallen" stomach or "fallen"

colon as symptomatic of ill health, when actually this was not the case.

Professor GOSTA FORSSSELL (Stockholm) urged the abandonment of the terms "hypertrophic" and "hypotrophic" as applied to the stomach, because these terms indicated an abnormal state, whereas both types were quite normal. One of these states was adapted to certain physiological conditions, and the other to certain different conditions, but equally physiological. Often in textbooks there was mentioned a hypertrophy of the pylorus in children, but as a rule there was no such hypertrophy. The condition did not really relate to the pylorus at all. It was really a case of contraction—perhaps sometimes a real hypertrophy—of the pyloric canal, not of the pylorus.

In discussing a paper by Dr DE BACKER (Ghent), giving the results of a radiological study of the digestive tract in normal children, Dr LE WILD (New York) said that the colon in children needed a great deal more elucidation. The statement that the long colon in the child would necessarily be outgrown was an error, this type of colon might persist throughout life.

*The Art of Palpation*

Dr A. E. BARCLAY (Manchester) said that palpation under the x-ray screen was a complex art, and one which was not acquired without much patient practice. It was not an art learned at the bedside, what it required was not only a delicate sense of touch, but a complex of touch and sight. It was of the greatest possible value in detecting the final changes in the stomach and other organs. The most important palpation of the stomach was that which was done while the first mouthfuls of food were passing down. Here a little pressure would often bring out a filling defect, more especially as to the margins. No matter with what care palpation was done, however, plates also were necessary. Radiologists should always attempt to show on their plates what they detected by palpation, and the success of a screen examination must not leave the radiologist content with faulty radiographic records.

*Diverticula of the Small Intestine*

Dr J. T. CASE (Battle Creek, Michigan) gave an interesting account, illustrated by radiographs, of some 70 cases of diverticula he had observed. One point was that in cases of multiple diverticula it was always found that the larger diverticula were nearest the stomach, and the smaller ones further away. By x-ray findings he had been able to differentiate between true and false diverticula. Of his 70 cases a number were found only at autopsy, some were found at operation for acute trouble apparently not related to the diverticulum. About three-fourths of the patients had no symptoms due to the diverticula, they died or they came to operation from some other cause, only in one-fourth did the need for operation arise or a fatal issue occur owing to pathological changes in the diverticula. In other words, the diverticula were subject to the same changes as the appendix.

*The Mucous Membrane of the Digestive Tract*

Professor FORSSSELL (Stockholm) offered some observations on the motor mechanism of the mucous membrane of the digestive tract, and showed some pictures demonstrating unmistakable variations in the relief of the mucous membrane in one and the same loop of the small intestine. He said that typical dissimilarities in the x-ray picture were not caused by different fillings, but by a real dissimilarity in the folds. He had tried to obtain more knowledge of the nature of the movements of the intestinal mucous membrane by means of direct observation, and he had found what he held to be convincing proof of the active participation of the mucous membrane in the movements which brought about a change in its relief. It seemed probable that the musculature would exhibit the

phenomenon of contraction at the place of the fold, he had made histological preparations of different parts of the alimentary tracts of men and of animals, and these had proved that the overlapping muscular cells in the muscularis mucosae occurred typically in the folds of the mucous membrane, being most marked at the tips of the folds, so that the muscularis mucosae within the area of the folds often attained a thickness several times greater than in the furrows between the folds. This phenomenon of overlapping was most marked in the stomach cavity, but it was quite distinct in the small intestine also.

Dr H. M. INNOMIS (New York) spoke on the observation of intermittent obstruction of the small intestines. This work, he said, depended upon screen examination, he was unable to make a diagnosis from the plate. The screen examination, moreover, had to be very painstaking, if it was to elicit the required information. The writhing and twisting of the duodenum and its marked inability to empty itself were perhaps the most characteristic signs.

#### *Radiology in Thoracic Surgery*

Mr. MORRISTON DAVIES (Ruthin) said that in thoracic surgery, where accurate diagnosis and localization were necessary as a preliminary to treatment, the clinical methods of examination were incomplete and not sufficiently discriminating. Radiology was not a substitute for clinical examination, but both in diagnosis and during the course of treatment it was such a valuable adjunct that treatment should not be carried on without resort to this method for checking the clinical findings. He referred to certain cases in which the diagnosis was possible only by x-rays. One patient was sent to him for bronchitis and emphysema, and clinically there was nothing suggestive of anything beyond those conditions, but on x-ray examination it was possible to diagnose primary broncho-ecarcinoma, for which the patient was operated on later. Another case was that of a girl with curies of the spine and with a little patch of dullness at the back of the right lung. By x-ray examination, and by that alone it was possible to make a diagnosis of hydrath of the lung. A woman who had been treated for thirty years at a general hospital for dyspnoea and palpitation, and was sent to him as a case of basal pneumothorax, proved on x-ray examination to have a diaphragmatic hernia. Another case was sent to him as early tuberculosis, and the x-rays showed a gumma in the upper lung. Another patient who presented only laryngeal symptoms was proved by x-rays to have military tuberculosis. The rays would frequently show greater changes than the hand or the ear could detect. Radiology was of equal importance during and after operative measures.

#### *Detection of Non-opaque Foreign Bodies*

A paper which called forth the special reclamations of the Section was read by Dr W. F. MANGES (Philadelphia) on the detection of non-opaque foreign bodies—usually nutshells and other hard vegetable substances—occasionally bones—in the air passages and food passages. Dr Manges's method was to watch the respiratory movements during inspiration and expiration, taking the x-ray picture at the full extent of both these acts, and by a comparison of the air entry to the lungs and the displacement of the mediastinum and heart he was able to arrive at the exact situation of the non-opaque body. The patients—usually children—were placed with the arms above the head, the face directly forward, the tube 36 inches distant and centred very carefully in the middle line, and the exposures were made as short as possible, the same exposure being given for expiration as for inspiration otherwise the impression of density on the two sides was unequal. The knack of making exposures at inspiration required to be developed—one had to learn to "shoot on the wing." The difficulty at expiration was not so great, because here there was a certain prolongation of the moment of rest.

#### *X-ray Examination of the Male Urethra*

Dr E. H. P. CAYE (Hullow) read a paper on the x-ray examination of the male urethra. The methuoscope although it must have first place as an aid to diagnosis

had certain limitations. With radiography it was possible to penetrate further and to visualize the whole course of the urethra. Cases of prostatic enlargement formed a group to which this method was applicable. The degree of enlargement of one or both lobes was clearly visible in the radiogram, and by repeated examinations the rate of growth could be determined. Similarly, in post-prostatic cases the contraction of the prostatic cavity could be observed by the same means. Radiography, again, could throw new light on the sphincteric action in normal and pathological conditions. He described the technique to be employed in using lipiodol, and the proper way of taking radiograms of the part. The injection was painless and discomfort to the patient was considerably less than that caused by urethroscopy or cystoscopy, and no ill effects, immediate or remote, were experienced.

#### *The Venous System*

Dr M. C. COSMAN (Boston) reported on a comprehensive study of brain tumours by means of x-rays. Certain of these tumours gave signs that furnished a clue, not only to their location, but to their type. In gliomas only 11 per cent might be expected to be seen radiologically, but pituitary tumours were characteristic, and meningiomas showed recognizable changes. In ten cases which came under his observation aneurysm of the intracranial portion of the internal carotid diagnosed radiologically had been confirmed either by operation or autopsy.

Among several other papers dealing with the localization of brain tumours and compressions of the spinal cord was one by Dr Jacques Loursin (Aix les-Bains), in which he described the value of radiologic diagnosis by the lipiodol method for localized compression in the spinal cord as well as for exploration of the bronchial tree. He said that lipiodol was eliminated after a time, and did not act as a irritant.

The papers on radiological diagnosis were so numerous that there was little time for discussion. Moreover, very many of the papers—and those some of the most valuable—were scarcely intelligently reported without the illustrations which accompanied them. Very frequently the illustrations overshadowed the text. This applies to such papers as that by Dr. H. J. P. Poir (Montreal) on normal varieties of bone simulating disease, to the very able paper by Dr. WOODWARD MORISON (Manchester) on diaphragmatic hernia to Professor KILMER's anatomical atlas of the x-ray signs in phthisis, and to the whole group of papers, chiefly by American and German authors, on cholelithography.

#### *Cinematograph Demonstration*

Two or three of the papers were illustrated by the cinematograph. Dr FRANKEL (Berlin) gave by this method a demonstration of a new symptom of ulcer ventriculi within folds. Dr L. G. COLE (New York) showed a long reel of cinematograph film, which had been produced under his direction, to illustrate the anatomy, physiology, pathology, and radiology of the stomach. The gastric cycle and the action of peristalsis were wonderfully well shown. All the ingenious devices of screen production, familiar to the public in the animated cartoon of which the immortal "Felix" is an example were employed to tell either the profession or the public—one was not sure which—everything that could be told about the stomach, and the film ended with some comic "business," in which a surgeon and a physician, supporters of rival theories, were left belabouring one another in true knockabout style! Dr Cole also showed a very elaborate film production illustrating tuberculosis, once again with all the brightness of subtitles and "close-ups," and the movement of inanimate objects—a curious and clever mixture of scientific demonstration and amusing entertainment.

#### *RADIOTHERAPY*

##### *Radiation in Cancer of the Breast*

Dr CASMAN (Antwerp) showed a remarkable cinematograph film illustrating the operation, in an actual case, of burning radium tubes in the breast. In cancer of the breast he favoured a combined method whereby x-rays,

radium, and surgery were all employed. Each of these agents used alone had its limitations. The difficulty with surgery was twofold: the unsuspected extent of the lesion and the anatomical impossibility of the extirpation of the tumour. The percentage of surgical successes left very much to be desired. The difficulty with  $x$  rays was to ensure that a sufficient amount of  $x$ -ray energy was absorbed in the tumour. Radium had a more limited field than  $x$  rays, but its action was more powerful. He began his treatment of a case with the  $x$  rays, making them embrace the whole area of infection as far as possible, thus, as he described it, "rounding up" the cancer. Some four or five weeks after the  $x$ -ray application he made a small "corner-shaped" incision and carefully buried radium tubes surrounded by gauze and fixed at a certain distance from the edges of the area to be treated. By using this method he had been able to employ an intensive radiation without menaces to the adjoining tissues, the radium being buried at some distance from the skin. In estimating the radium dosage the  $x$ -ray irradiation which the tissues had absorbed must not be lost sight of. Dr. Casman contented himself with the film demonstration of his technique and did not enter upon a discussion of comparative results.

Dr. BURTON J. LEE (New York) gave a report on a series of eight primary operable cases of carcinoma of the breast from the Breast Clinic of the Memorial Hospital in his city. All these cases had been treated entirely by irradiation, without surgery at all. A period of four and a half years or longer had elapsed in each of the cases since treatment was begun. The reason for withholding surgery was either the age of the patient or her refusal to submit to operation. He had to confess, however, to a considerable pessimism with regard to the end results of surgery in the treatment of mammary carcinoma. In this group of eight cases the oldest patient was 90 years of age, by the introduction of radium tubes she was made comfortable for three years until her death from intercurrent disease. The average age of the patients was 58, the rate of growth of the disease in six of the patients was slow, and in two moderate. Axillary nodes were palpable in two of the patients. In the three cases in which biopsy was done the result showed carcinoma simplex. Three of the patients were treated entirely by  $x$  rays, of these one was alive, and the other two had died respectively two years and four years following treatment. Radium was used alone in two patients, and radium and  $x$  rays combined in the other three. The radium used was approximately 1 millicurie per cubic centimetre, and the  $x$  rays were from a low-voltage tube, 6 min. exposure, focal skin distance 10 in., filtration 3-4 mm. aluminium. Of the eight cases five were now alive and well, two had died from intercurrent disease, and one of metastases. He held that radiotherapy was the treatment of choice in primary operable carcinoma of the breast in those of advanced age, and was justifiable if surgical intervention was refused, the results in this limited group of cases might be compared with the results obtained in surgery without disadvantage to radiotherapy.

#### *Inoperable Carcinoma of the Cervix Treated by Radium*

Dr. MALCOLM DONALDSON reported on 85 cases of inoperable carcinoma of the cervix treated by radium. His paper embodied the conclusions given in his article in the *BRITISH MEDICAL JOURNAL*, May 9th (p. 876). He added that he was still in doubt as to whether it would be better further to increase radium intensity (either per unit of needle or by inserting more needles) or to increase the duration of application. Although the cases treated by his latest technique were an improvement on the previous ones, yet in those cases which were not doing well the site where growth went ahead was more often in or around the portion of the rectum lying beneath the vagina. It had occurred to him that this was due to the fact that the intensity in that area had been too much diminished in the effort to get the bulk of the radium against the more localized growth in the broad ligaments. In his next series of cases he intended that the time factor should be the same—namely, 144 hours—but that the number of needles should be increased, several being placed around

the lower part of the rectum. He realized that by so doing a great deal of proctitis and even fistulae might be set up, but possibly the fear of this complication had been the cause of this portion of the body being left at the mercy of the cancer cells.

The paper was discussed by Professor DAELS (Ghent), Dr. BURTON LEE (New York), Dr. M. R. J. HARRIS (Dublin), and others. Dr. ZWEIFEL (Munich) said that at his clinic radium had been used in cancer of the cervix, but subsequently a combined method of radium and  $x$  rays was chosen. Among the operable cases there had been 43 per cent. of cures, and among inoperable ones 7 per cent. of definite cures. He hesitated to include the more recent cases, but he believed the proportion of cures would prove to be higher, thanks to the combined method now used. Professor HERMANN WINTZ (Erlangen) said that squamous carcinoma of the cervix was much more sensitive to  $x$  rays than to radium.

#### *The Encirclement Method of Radium Treatment*

Mr. SIMPSON HANDLEY (London) described his encirclement method of radium treatment. He said that every aggregation of cancer cells had a definite life cycle, and after increasing in size for a varying period and at a varying rate tended spontaneously to undergo fibrotic changes. The centre of a mass already degenerating or dying would succumb to a much smaller radiation dose than the actively growing periphery. Attention might almost be concentrated on the periphery and the central portion left to take care of itself. The disappearance of a lump of malignant tissue was not of so much importance as the arrest of its spread. In addition to the spread of a nodule by infiltration, cancer cells spread by permeation of the lymphatics, a process which, when once it started, would outstrip the process of infiltration. Often it was best to ignore altogether for the time being the visible deposit and to direct attention entirely to the zone of infiltration and of permeation surrounding it. The radium tubes should be so arranged as to give a lethal dose to that zone. Afterwards, if the nodule had not disappeared, a second irradiation might be given in a narrower circle, and later still, if a vestige remained, another irradiation on the nodule itself.

#### *Malignant Disease of the Upper Air Passages*

Mr. DOUGLAS HARRIER (London) said that sarcomas of the upper air passages, especially those of the round-celled type, invariably reacted well to radium treatment. He spoke of cases which had been treated in this way five years ago, and were now completely well and apparently cured. In endothelioma there were some equally remarkable results. In this condition radium might be taken as having diagnostic value. If a tumour was a true endothelioma it would almost entirely disappear under radium. Radium was not equally successful in all diseases of the upper air passages, but in carcinoma of the larynx and some other conditions he thought that surgery by itself had seen its day.

Dr. C. REGAUD (Paris Radium Institute) spoke of the treatment of epithelial cancers of the tongue and floor of the mouth. Out of 174 traceable cases in which treatment had taken place from one to five years earlier, 42 were alive and without any symptoms of cancer—50 per cent. of these had been operable cases and 34 per cent. on the border-line—and another 39 showed healing of the localization in the tongue and apparent sterilization, but had died or were expected to die of adenopathy. The principle of treatment had been to distribute numerous weak radio-active foci in and immediately around the cancerous part, to use the gamma rays only, and to give continuous irradiation over a long time.

#### *Radium Therapy in Various Conditions*

Dr. S. A. HEYERDAHL (Oslo) spoke on actinomycosis treated by radium. His first case, before coming for radium treatment, had been operated on twice without permanent result. Radium treatment was tried in 1913, and after ten years there was no relapse. Later he had had the opportunity of treating 17 men and 4 women with

radium, giving usually two or three applications with intervals of six weeks. In all cases there were good results, which had continued up to the present, the treatment dating back for from two to ten years.

Dr F. TOMISIK (Pisguc) gave an account of the treatment of pernicious anemia by radium. He had tried to diminish the activity of the spleen by massive irradiation over long periods, and he had succeeded in twenty cases in which other methods, including blood transfusion, had not succeeded at all. He recommended radium treatment in preference to splenectomy. He also gave an account of the effects of prolonged irradiation in Pisguc during the last few years he had employed a method of protected radium irradiation of the spleen, using 2 mm zinc filters, at a distance of 3 cm. He used 80 to 100 mg of radium, dividing up the tumour area into twenty five small fields and treating each field successively for one or two days. The blood picture greatly improved. Dr R. H. STIVERS (Detroit) said that during the past year he had treated four cases of leukaemia with intravenous injections of radium in order to get the prolonged action of comparatively small doses. Three cases had not been very successful—two, in fact, had died. But in the fourth case the injection of 200 mg was given last October, with marked improvement in November, and the patient had another 200 mg in January. Before the first treatment his blood count was something like 200,000 leucocytes, but since the second injection it had been normal. This patient had previously been irradiated for five or six months, but did not seem to respond, and that was the reason why intravenous injections of radium were given.

Altogether about thirty papers were contributed on the subject of radium, some of them recounting a single observation and others founded on a vast experience. Among the latter was the paper by Professor A. BAYER describing the practice at the Brussels Radium Institute in treating various cancers by a combination of surgery and radium and sometimes a ray also. The total number of cases so treated during two recent years was 742. The results had been particularly satisfactory in cancer of the rectum and cancer of the uterus. He insisted that no one method must be considered as subordinate to any other. He did not approve of the subordination of radium therapy to surgery, as practised in France and in other countries.

#### X-Ray Treatment of Breast Cancer

Professor HERMANN WITZ, of the Erlangen Clinic, described the results in 106 cases of breast cancer treated by x rays which had been observed for a period of three years following treatment. He divided the cases into three groups: (1) those in which the tumour was restricted to the breast and could be moved, and in which there was no infection of axillary or supraclavicular glands, (2) those in which the tumour had already infiltrated the surrounding region, and axillary glands were palpable, (3) those in which the glands in the supraclavicular region were palpable, and in some cases metastases were also apparent. The cases were those in which on careful examination no trace of cancer could be found, "lost" cases those in which the patient had died or was in a dying condition, and those who could not be followed up.

Group (1)	Treated	Cured	Lost	Clinical Cure
Group (2)	21	20	1	95.2%
Group (3)	41	28	13	68.2%
	44	8	36	18.1%

He noted that in groups (2) and (3) the results were better than in surgical statistics. It was essential that the requisite dose for the destruction of the carcinoma cells should be applied to the axillary and supraclavicular regions as well as to the tumour itself, and of equal importance was a carefully planned scheme of after-treatment. Care must be taken to avoid lung fibrosis, and by adjustment had been brought down to 5 per cent. He found the percentage of successes in primary x-ray treatment considerably greater than in prophylactic x-ray treatment after operation, and he had abandoned prophylactic x-ray treatment in the strict sense of the word, preferring to wait until the nodules on the skin or the gland metastases gave pronounced indications for treatment.

Dr DOUGLAS WINSTON brought forward the results of x-ray treatment in 15 cases of operable carcinoma of the breast. At the present stage irradiation should not be advised in preference to operation or operation was made when patients refused to discuss the technique and results of irradiation treatment. Eight of his cases had been treated solely by x rays, two with radium insertion and x rays and five with surface applications of 0.5 gram radium element and additional x-ray applications. The interim results of the cases were too recent for detailed conclusions—suggested that radiation was a suitable alternative to operation in some operable cases, and the other of the disease itself intrinsically, and the other had been discontinued after two years after treatment had abdominal metastases after a patient. One patient had never cases, but one had been acting well locally. Three were new cases, but one had showed no signs of the disease. In the remaining nine cases the general and local condition had taken place or was true that surgical statistics came out very badly by this criterion, but Professor Wintz's figures, on the three year basis would always appear much too good, although, on the other hand, statistics after five, six, or seven years would tell unfairly the other way, because the methods of application had greatly improved since those early days.

#### The Stimulating X-Ray Dose

Dr R. H. ZWERNER (Munich) opened a discussion on "The stimulating dose." He described a number of experiments by various workers which went to prove the existence of such a dose. It had been shown that plant exposed to small doses of x rays grew more quickly than normal controls. Russ and others had found by experiment on mice a positive stimulation effect. In the irradiation of the tissues in fibroid an increased loss of blood had been noticed, especially when the treatment was given shortly before the period of calving after x-ray exposure. Nearly all malignant tumours could be influenced to more or less increase of growth. In a large number of cases of cancer of the uterus treated at the clinic at Munich many cases of commencing cancer, which if untreated would have lived at least a year, died within a shorter time—even as short as six months—after radium and x-ray treatment, and such cases suggested that it was the radiological interference which had led to the quickened growth. The dose applied in the depth had not been sufficient to kill the growth, but, on the contrary, had stimulated it.

Dr I. S. HENSEN (New York) thought that it was necessary to distinguish between the effect on the cell as an individual unit, on the tissue as a cell complex, and on the organ as a tissue complex. There was no question but that the effect on the individual cell was always in the nature of a "stimulus," an "insult," but in the complex structure of the tissue there came into play compensatory powers which might result in stimulation rather than destruction. Dr DOUGLAS WINSTON (London) said that it was clear from the examination of buds and plants under the microscope that there was a stimulation dose. There were also certain clinical cases which appeared to point to a stimulation dose, and it was dangerous to assume that there was no such dose without absolute proof of its non-existence. Professor WITZ (Erlangen) said that it was only a certain dose, measured by biological standards, which was stimulating. It appeared that 40 per cent of the unit skin dose might be considered a stimulating dose for a squamous-celled carcinoma. Professor BECKER (Paris) said that recent French research had shown that there was a stimulating action, but that it was feeble and of short duration. The effects might partly be due to secondary infection of a microbe character.

#### Methods in X-Ray Therapy

Dr G. E. FRAHLER (Philadelphia) described what he called the saturation method in x-ray therapy. The principle of it was to repeat x-ray doses at short intervals in order to maintain the erythema dose—which in the case

of unfiltered rays fell by 50 per cent in value in about three days—it approximately its original level. Thus, malignant cells while still undergoing division, received the prolonged maximum action of the rays. This method, which had advantages over the single massive dose, required careful measurement of the quality of radiation and accurate direction of "cross fire."

Dr ISAC GERBER (Providence) spoke of the usefulness of minute doses of filtered radiations in superficial progneic infections, particularly of the skin. Needle infections of surgeons had been completely aborted or promptly circumscribed by x-ray treatment. Deep phlegmons and cellulitis would localize very quickly, erysipelas also yielded to this treatment. The dose given was never more than 25 per cent of the skin erythema dose, and was as low as 6 per cent in children. This dose was simply applied to the surface, and in a great many cases a single exposure sufficed. Dr W. MICHURILL (Bradford) referred to the need for adequate filtration when attempting to deal with the conditions. Dr SCHNARUS (Düsseldorf) had proved that the excellent effects of x-rays in furunculosis were caused by an immunity to the staphylococcus developing after irradiation.

**Effect of X Rays on Mitosis in Tissue Culture**  
Dr T. S. P. STRANGEWAYS and others who have been working with him gave a demonstration of their researches on the effect of irradiation on living tissue cells *in vitro*. The ultimate object of their work has been to find the optimum dose of radium or x-rays to destroy a cancer. They also exhibited stained specimens which showed the effects of exposing the cells to radium or x-rays. These brought out the effects of the radiations on actively dividing cells at certain distances and for certain times. A further demonstration given by these workers was of the internal structure and movements of the actual living cell, shown by means of dark-ground illumination.

#### ACTINOTHERAPY

SIR HENRI GAUVERIN opened a discussion on actinotherapy. He said that the treatment by light was based on clinical experience and observation. Use should be all means be made of the results of discoveries with regard to the action of light on the body, but these discoveries, sometimes apparently contradictory, must not be allowed to deflect the clinical judgement. The clinical result of the treatment given was the final thing to be considered. He himself was in the habit of describing the action of light as twofold—first, on the mind, and, secondly, on the body. At Alton it had been possible to demonstrate that, with exposure to light, there was a definitely increased response of mental health. With regard to the effect of light on the body, he thought it might be described as twofold. There was first the direct or local action, the effect of light on the skin, which was of various kinds, including inflammatory response and the formation of pigment. Some workers went so far as to urge that pigmentation should be avoided, but he believed that pigmentation should be important therapeutic significance. Patients who had a very marked well so frequently did well in other respects that there must be some association between pigment formation and therapeutic effect. Then there were the remote or indirect effects of light, with regard to which he did not propose to speak. There had been a tendency, especially in this country lately, to use very short-wave ultra-violet rays. These had a rapid and remarkable action, but very little penetrative power. He reminded the Section of the antagonism of rays—some rays appeared to stultify the effect of other rays. In fact, light therapy was in some ways the most intriguing of the therapies because of the unexpectedness (even if occasionally the confusing character) of some of its results.

Dr LEONARD HILL (London) gave what amounted to a lecture in this Section on sunlight and artificial sunlight treatment. He mentioned, among other matters, how entirely the effect of ultra-violet rays was screened off by garments, even by the thinnest zephyr. Artificial silk was the most permeable material, being an acetocellulose, whereas natural silk was a protein. If the patient receiving ultra-violet treatment insisted on being clothed the garment

should be an artificial silk zephyr. He went on to point out how little danger from sunburn existed in the smoke-polluted air of English cities, and gave some figures illustrating the striking differences between various localities, even between places so near together as Hampstead and Kingsway, at this last station the ultra-violet rays were not then minimum. There was no need in England to take all those precautions against sunburn which Rolher had found necessary at Leyden. Dr Leonard Hill described the action of ultra-violet radiation on the tissues, saying that it put up a general resistance, not a specific immunity, to infection.

Professor SEVER (Copenhagen) spoke of the action of ultra-violet and visible rays in therapy, and especially how visible rays, penetrating into the skin, heated up the subcutaneous blood. He also insisted on the advantage of radiant visible heat, such as the open fire or the gas fire. Dr R. G. BANNERMAN (Alton) dealt with some of the biological effects of mercury vapour lamps. It would appear that a massive dose of mercury vapour radiation was followed by a phase of depression of the organism, and therefore, while an erythematous reaction might be desirable or even essential in the local treatment of a local condition, it was to be avoided in the treatment of a general condition.

Dr S. ROTUNDO brought forward the results of some experimental research carried out at Giessen University dermatological clinic. The work had shown that in the case of light baths intensive reaction of the skin must be avoided on account of the danger of focal reaction. By combining light treatment with systematic hydrotherapy, massage, and exercises in the sun or in the artificial light bath, the best results were secured. Natural sun baths were best, with quartz lamps it was more difficult to make the pigmented skin hyperemic. It might be that the visible spectrum had a helpful effect, but without ultra-violet radiation no therapeutic effect was possible, whereas the visible rays could be dispensed with.

Dr A. EMMERSON (London) spoke on the bactericidal effects of ultra-violet rays, these effects could be seen when a very thin film of blood containing bacteria was exposed to an ultra-violet source. When photosensitizers such as eosin were added to the mixture of blood and bacteria the direct bactericidal action could take place upon exposure to visible light. Direct exposure of defibrinated blood to ultra-violet rays destroyed the bactericidal properties of the irradiated and slightly haemolysed after one hour's irradiation, and examined by the spectroscope, the presence of methaemoglobin could be detected.

Dr MORRIS LEVICK referred to the importance of red light as a physiological and curative agent. The red rays were absorbed by muscle and, he believed, by inflammatory exudate. Carbon filaments yielded a light much richer in red and infra-red frequencies than the ordinary metal filament, and the infra-red rays could be cut out by red-stained soda glass screens. To avoid undue heating the lamps should be placed at a distance of two feet, allowing of free circulation in the air around the part. He cited the value of red radiations in cases of musculo-wasting, tuberculous ulcerations, and other conditions.

#### Electrotherapy

One of the three discussions in this Section was devoted to electrotherapy, and was opened by Dr E. P. CUMMERBATCH, who referred particularly to diathermy, and continued by Dr WILLIAM BIERMAN (New York), who described his method of surgical diathermy in the treatment of haemorrhoids, which, he said, was a marked improvement on the cauterization that it caused less injury to the tissues and introduced heat in the most effective way. Dr S. JELLINEK (Vienna) gave an account, illustrated by some remarkable microscopic slides, of the bone changes, immediate and delayed, occurring after electrical shock.

**International Units and Standards**  
The opening of the combined discussion by the Sections of Physics and Radiology on international units and standards for x-ray work was reported last week. A great

[2 JULY 11, 1925]

# INTERNATIONAL CONGRESS OF RADIOLOGY

[The President  
of the Congress]

part of the discussion dealt with the technique of physical measurement in a way which does not lend itself to a useful abbreviation. The feeling evident throughout the discussion was in favour of setting up a standard which should be expressed in terms of absolute units. Perhaps the most helpful thing was said by one of the British physicists, who declared that the necessary preliminary to a really universal system of measurement would be to arrive at a constant source of current for the tube. If a standard type of x-ray beam with a constant voltage apparatus were available, that beam could be measured in terms of the international unit, whatever that unit might be. The outcome of the discussion was a resolution to appoint an international committee to study the question of measurement. This committee was not appointed at the Congress, because it will be necessary to communicate with the various scientific bodies throughout the world in order to arrive at a representative membership, but it was agreed that the following gentlemen, who constituted the British X-Ray Unit Committee appointed in 1923, should form a group to nominate the international committee: Sir William Bragg (Chairman), Professor F. L. Hopwood, Dr. E. A. Owen, Mr. C. E. S. Phillips, Professor A. W. Porter, and Professor Sidney Russ.

## Silvanus Thompson Memorial Lecture

In the course of the Congress the eighth lecture in memory of Silvanus Thompson, founder of the Röntgen Society, was delivered by the Duc de Broglie, the well known French physicist, who is a doctor honoris causa of the universities of Oxford and Leeds. His general subject was the absorption of x-rays and gamma rays and the secondary rays which accompany them. The lecture was a review of recent work and a description of the lecturer's own investigations on x-ray absorption spectra. He said that it was now possible to begin to describe a definite wave-length to the gamma rays, the absorption of which resembled closely x-ray absorption, with certain differences, however, which were very curious to observe in the cloud-expansion apparatus, and might perhaps help eventually to explain the difference between the observed effects of the two radiations. In the concluding part of his lecture the Duc de Broglie suggested that there might be a kind of "trigger" effect of radiation on living cells. On these deep problems ignorance had to be confessed, but there was little doubt that the joint efforts of biologists and physicists would sooner or later cause some ordered conceptions to emerge from the present obscurity. A vote of thanks was recorded on the motion of Dr. A. E. Barclay, seconded by Dr. KAYE.

## Protection of X-Ray Workers

Dr. G. W. C. KAYE (National Physical Laboratory) opened a discussion in the Physics Section on protective and manipulative methods. He said that although the radiologist was not likely to tempt Providence by foolhardy exposure, he did not always appreciate the results of scattered radiation. Radiation was given off from the body of a person who was being subjected to x-rays, and the scattering produced by the air in the room in the vicinity of the x-ray tube was something like that of the primary radiation. If the scattering was excessive the operator should be behind a screen or wall. Each outfit should be protected by walls extending from the floor to the ceiling, and floor and ceiling should also be protected. The protecting lead for a strength not exceeding 70,000 volts should be at least 1 1/2 mm. thick and for 100,000 volts 2 mm. thick. There was a danger in using gamma rays to test the protection of materials, as these made the protection appear much better than it actually was. All protective boxes should be tested for leakage. He was surprised that the open bulb was still being used, as in many cases it was often possible to take a radiogram of the hand in any part of the room. Generous ventilation of the x-ray rooms had an importance second only to that of protection, and nausea, floor space should be adequate, and the material should be wood, cork, or rubber. M. PIRON (Paris) spoke on the same subject, and described an oil-immersed tube, of the same size as the

Coolidge universal tube, which could withstand 200,000 volts on the direct current. Every part of the glass wall was cooled and had the same temperature. After the box was earthed the patient ran no risk of receiving an electric shock. Mr. V. I. PIRNIS (director of radiological research, Woolwich), who said that he had to do with x-ray protection in fifteen service hospitals, laid stress on the need for efficient ventilation. He also related an instance in which several patients in a ward above an x-ray room had ulcer on the heel after leaving having reached them through the ceiling.

## The Organization of a Hospital Radium Service

Professor L. L. HOLLOWAY (St. Bartholomew's) described the organization of a hospital radium service. The radium of which he was in charge was distributed among 220 containers. He illustrated the various holders, thermometers, and magnifiers for reading identification marks on the needles—all conceived to avoid handling the radium—also the ingenious drawers, lead encased, in which radium was kept. He submitted a list of the regulations operative in the hospital. Dr. G. FAIRLIE (New York) said that in his hospital colour was largely used for identifying tubes at a distance, and in that way no open wounds resulting from the manipulation of radium had to be dealt with, though the fingers, especially around the nails, became red and scaly.

## Exhibition of Apparatus

During the four days of the meeting an excellent exhibition of apparatus and accessories associated with x-ray work and electrotherapy was held at the Central Hall, to which over thirty firms contributed.

## THE CONGRESS DINNER

The Congress dinner was held at the Hotel Cecil Central on Thursday evening, under the presidency of Mr. C. THURSTON HOLLAND, who was supported by Sir Humphry Rolleston, F.R.C.P., Dr. E. M. Callender, President of the Medical Society of London, Sir Robert Jones, Sir Dawson Williams, and other members of the Committee of the Congress and the officers. Representatives of seventeen countries were present.

The President recalled the early days of Röntgen's epoch-making discovery, less than thirty years ago. Soon after the discovery was announced the speaker became possessed, through the generosity of his great friend, Robert Jones, of a complete x-ray apparatus—cost outfit—coil, tube, tube stand, and electrical supply—less than £30. Nowadays a young radiologist, if he desired to practise all the branches and to the full extent, would require an outlay on instruments of approximately £3,000. The early work on radiology was done by a band of youngish men, all comparatively unknown in medicine and surgery, who had to fight to a large extent against prejudice, and to wait a considerable time before they were able to establish radiology as a means of diagnosis—to say nothing of treatment—in the position it now held. But what would medicine and surgery be at the present day without radiology? Many of that band of youngish men had suffered physically, some had lost their lives. Quite recently radiology had had to mourn some great figures whose lives might have been prolonged had their enthusiasm been less—Leonard of Philadelphia, Albert Schonberg of Hamburg, Bergamo of Bordeaux, and in this country Archibald Reid. To-day it was possible for a young man to start on a career of radiology without taking any of these risks, what was more, he could start with the advantage of the knowledge that the older men could impart. He could take diplomas in radiology at two universities—Cambridge and Liverpool—and soon he would be able to take a diploma at a third—Edinburgh. Nevertheless, the speaker did not envy the young men. It would not be theirs to know the thrill of discovering for the first time a stone in the kidney, or of seeing as a novel thing the outline of the stomach under the opaque meal. Yet, no doubt, there was much still to be done, perhaps only the threshold had been reached, and if such congresses as the present were to be repeated, and such work had a joy which money-making could not give. The President concluded

with a tribute to some of the men behind the Congress—to Dr Robert KNOX, the moving spirit, the Presidents of the three co-operating bodies, Dr Barclay of the Roentgen Society, Dr Melville of the Electro-Therapeutic Section of the Royal Society of Medicine, and Sir Humphry Rolleston of the British Institute of Radiology, the honorary treasurer, Dr James Metcalfe, and the joint secretaries, Dr J. E. A. LANHAM and Dr JOHN MUNN.

Delegates from the different countries then expressed, most of them in one or two sentences, their appreciations.

Professor C. BÉCLÈRE, speaking in French, after an eulogy of the organizers of the Congress, referred to the appropriateness of the portrait of Roentgen on the dinner card. He said that this was an act of justice and of gratitude, a proper homage to the intellect of the scientist and the character of the man. What portraits might accompany that of the great Roentgen at future Congresses? He hoped those of Henri Becquerel and the Curies, whose discoveries had opened a new domain to radiology. Such a group would be an eloquent symbol of the intimate bonds which united great discoverers, and a testimony to the fact that this science of radiology, like other sciences, was a collective piece of work, an achievement to which men of many different countries contributed—here and there a man of genius, but also, not less to be regarded, a multitude of modest workers animated by the same spirit. It was essential that the co-operation in science of men of different nations should become closer, more active, and more powerful. One of the necessary conditions for the progress of radiology was the *entente* between radiologists of all countries.

Professor HANS DIETLEN, speaking for German radiologists, said that internationalism had always been a necessary condition of effective culture, and his countrymen were grateful for the opportunity of participating in this gathering.

Professor M. NEMENOV (Russia), who spoke in German, said that the Russian delegation came from a far country after a political earthquake, and were hardly sure of their reception, but it was enough for them to exchange the first few words to know that they were in hospitable company.

Professor CARL SONNE (Denmark) said that his country was the first to place actinotherapy on a firm scientific basis, and he was glad to find actinotherapy represented by a section in the Congress. Dr L. F. DRIESSEN (Holland) said that he spoke for a small country, but he was glad to point to the disproportionately large attendance of members of the Dutch Roentgenological Society, of which he was president. Professor GÖSTA FORSSELL (Sweden) said that the Congress was a model to all future international meetings, but those who entertained subsequent Congresses would be hard put to it to reach the high level of British hospitality. Dr P. M. HICKEL (United States) presented the felicitations of American radiologists on "pulling off" such a wonderful Congress. If the statesmen and editors of the world would take a lesson in brotherly love from the scientific men the troubles of the world would very soon be straightened out.

Others who responded more briefly were Dr CARLOS HEUSEN (Argentina), Professor A. SCHÜLLER (Austria), Professor DE NOBELE (Belgium), Dr HOWARD PIRIE (Canada), Dr W. ALTSCHUL (Czechoslovakia), Dr M. PONZO (Italy), Mr M. R. J. HAYES (Irish Free State), Dr S. A. HEYERHAEL (Norway), Dr J. DEBICKI (Poland), and Dr R. FEISSLY (Switzerland).

#### MACKENZIE DAVIDSON MEMORIAL LECTURE

The Mackenzie Davidson Memorial Lecture, held under the auspices of the Electro-Therapeutic Section of the Royal Society of Medicine and the Roentgen Society, was delivered by Sir BERKELEY MOYNIHAN on Friday evening before a very large gathering. Among those present was Lady Mackenzie Davidson. Sir Berkeley Moynihan's lecture on "The relationship of radiology and surgery," is printed in full at page 47 this week.

Dr STANLEY MELVILLE proposed, and Dr A. E. BARCLAY seconded, a vote of thanks to Sir Berkeley Moynihan, and Mr THURSTAN HOLLAND, who presided, presented him with the Mackenzie Davidson memorial medal amid much acclamation.

## NATIONAL ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS

### ELEVENTH ANNUAL CONFERENCE

THE eleventh annual conference of the National Association for the Prevention of Tuberculosis was held at the house of the Royal Society of Medicine on July 6th and 7th, under the presidency of Sir ARTHUR STANLEY. The proceedings were opened by Sir KINGSLEY WOOD, M.P. (Parliamentary Secretary to the Ministry of Health), who expressed official appreciation of the work of the association and of its character as a voluntary body.

Visitors were present from the United States, Denmark, Austria, and Russia. The Russian representative, Dr VONEBELFF (Moscow), said that the health of the Russian population was rapidly improving, and the campaign against tuberculosis was now organized on a large scale. The propaganda found successful in England was being followed, and the people were encouraged to active participation in health work. Dr WOODS HUTCHINSON (United States) spoke eloquently on the decline of tuberculosis as a result of sanitary skill and enlightened public opinion.

Sir ARTHUR STANLEY said that the association, responding to a suggestion made at the last conference by the late Minister of Health (Mr John Wheatley), had drawn up a memorandum on the establishment of model workshops for the tuberculous community, but owing to the change of Government and the pressure of public work the matter was in abeyance. The propaganda of the association had gone steadily forward. A vote of thanks to Sir Arthur Stanley for his services as chairman of council was recorded on the motion of Sir ST. CLAIR THOMSON, seconded by Sir HUMPHRY ROLLESTON.

#### Tuberculosis in Childhood

Two subjects were before the conference, one of them "Tuberculosis in childhood," and the other "The treatment of tuberculosis by sanatorium." Professor PIQUET had been announced to open the first of these discussions, but owing to illness in his family he was unable to leave Vienna, and his paper was read by Dr Richard WAGNER, of the children's clinic in that city. Professor PIQUET made use of the statistics of the Registrar-General for England and Wales to show the enormous significance of tuberculosis as a cause of mortality at the most efficacious period of life. It appeared to assert itself as the chief mortal disease from the age of 10 up to the age of 46. Dr WAGNER also read a paper of his own, on the nutritional treatment of tuberculosis in childhood, in which he gave some statistics of the morbidity from this cause in Vienna and Lower Austria. He described also the nutritional classes at the children's clinic, and the results which followed.

Dr A. STANLEY GRIFFITH dealt with the bovine tubercle bacillus as an important source of human tuberculosis. The highest percentage of bovine infections was found in children under 5 years of age. It would be difficult, though not impracticable, to free the whole country from bovine tuberculosis, but until the ideal of tubercle-free herds was attained universally all milk not from such herds or not efficiently pasteurized should be sterilized in the home before being given to infants, children, or sick persons. As to the objection that bovine tubercle bacilli in milk might confer an immunity to the more dangerous human infection, he thought there was no evidence that the absorption from the alimentary tract of small numbers of bovine bacilli had any significant or lasting immunizing effect. Dr C. RIVIERE said that in modern civilized communities repeated infection with the tubercle bacillus was inevitable. This infection led to immunity and protection against the disease. The primary infection was of importance, and probably determined the whole future *qua* tuberculosis. Infection in early infancy was dangerous and postponement was valuable, but could only be temporary. The infection might be with the highly virulent human strain, commonly by the air passages, or with the bovine strain, comparatively innocuous to man, by the alimentary tract. Was it worth while to withhold this latter source of infection knowing that the alternative was the dangerous

human type of the bacillus? Nevertheless, he hoped that some day public opinion would be ripe for a less clumsy procedure of tubercle immunization than the giving of milk.

SIR ROBERT PHILLIP spoke of the lines on which preventive treatment of the child had proceeded of recent years. The Giancher method, by which delicate children were transferred from dubious home environment to presumably healthy surroundings in the country, was subject to the fallacy that most of the children thus taken in hand were already tuberculous, and the excellent results following the system were to be attributed to a progressive detubercularization along natural lines. Another proposal was that prior to "spontaneous" infection the child should undergo artificial inoculation in order to anticipate the effect of exposure, but it had yet to be seen to what extent, in the absence of disease, parents would consent to submit the newly born infant to inoculation with tubercle bacilli, however modified, and however simple the process might be. His own plan of "anticipatory detubercularization" proceeded on the assumption that infection took place practically always during childhood, that the occurrence of the subsequent process of tubercularization might be definitely determined, and that it was possible to limit and counter the process by detubercularization. His method had two aspects—environmental and antigenic. The results had been described by him in the *BRITISH MEDICAL JOURNAL* (March 24th, 1923).

Among other speakers Sir WILLIAM THOMPSON referred to the drop in child mortality from tuberculosis during recent years in the Irish Free State, Dr FRANCIS HEWAT related some experiences from the Edinburgh Royal Infirmary, and Professor LOUIS McLEOD dealt with the provision for infected pregnant women.

On the second day of the conference, with Sir ROBERT PHILLIP in the chair, the discussion was continued, and Sir HERMAN GAVAN gave an address on the prevention, treatment, and after-care of surgical tuberculosis in children. He refused to believe that bovine tuberculosis could not be relegated to the horrors of the past. The argument that drinking slightly infected tuberculous milk would enable one to acquire immunity to infection he described as a dangerous and unnecessary doctrine. Dr GORDON PUGH followed with an illustrated description of the constitutional treatment of early non-pulmonary tuberculosis as carried out at Queen Mary's Hospital for Children at Carshalton, and showed the special spinal and hip frames and carriages designed to facilitate the application of heliotherapy, arc-lamp treatment, and gymnastic exercises, while immobilizing the diseased part. Professor JOHN FRISER referred to the relative incidence of surgical tuberculosis among town and country children. In Scotland the disease was more frequent among dwellers in the country. In the cities the organization of milk inspection was thorough, in the country it was too often a dead letter.

After some general discussion the conference unanimously passed resolutions urging the Government to use every possible means to render effective all the provisions enacted in the Milk and Dairies Acts of 1914 and 1922 and the subsequent regulations, also asking the Ministry of Health and the Board of Education to consider the desirability of including in school education more definite instructions regarding the principles of health conservation, personal and communal, and simple methods for the prevention of tuberculosis.

#### *The Sanoerysin Treatment*

The final session was concerned with the treatment of tuberculosis by sanoerysin, and was almost entirely occupied by lectures, each of an hour's duration. Professor HENRI MOELLGAARD of Copenhagen recapitulated the principles and results of the treatment, as set out in his recent article in these columns.<sup>1</sup> He added that up to the time he wrote his paper he believed that sanoerysin had no influence on surgical tuberculosis, but some evidence had come before him during the last few days that in suitable doses it was effective here also. The results of his

veterinary experiments had been supported by some recent researches made in the Danish State Serum Institute, and reported by Dr MADSEN in May last.

Dr KARL LARSEN (Professor of Clinical Medicine, Copenhagen University) described experiences with sanoerysin treatment during the last seven months in the university clinic. Before coming to the results he dealt with the reactions and dangers of the treatment. The treatment resolved itself into a short series of injections, the effect of which on the patient's temperature diminished with each injection. The greatest risk was the occurrence of the acute stage of shock described by Professor Moellgaard, the shock was most likely to occur when the injection was given while the patient still had fever reaction from a previous injection. The danger of the treatment really consisted in following the injections too rapidly upon one another, with consequent accumulation. He advised a less intensive treatment than the one originally proposed, so that the harmful effects might be reduced and controlled. In grave febrile cases it was necessary to be particularly cautious. Dr LARSEN then showed charts and x-ray photographs relating to a small number of cases of pulmonary tuberculosis in which a decidedly favourable effect of the compound was seen. Apart from improvement in the general condition—the cessation of the febrile or subfebrile state—there were certain objective changes, particularly the disappearance of rales, freedom of the expectoration from bacilli, and improvement in the x-ray picture. The material was as yet too small and heterogeneous for conclusive statistics to be furnished, but an estimate was possible in about 40 cases coming under his own observation in which the treatment was finished or almost finished. Eight of these patients must be regarded as clinically cured, 17 showed very considerable improvement, 9 still showed signs of active phthisis after six months' treatment, and in 6 patients the disease had not been arrested at all, but rather had tended to spread. The best results were obtained in patients who had been suffering for less than a year from the illness. During the last twelve months the treatment had been employed in Danish sanatoriums, and here the statistics, relating to 250 cases in which the treatment might be said to be finished, showed decided improvement in 52 per cent. It was still too early to give a pronounced and final verdict, but it seemed to him that the compound was able to bring about in many patients a pronounced and rapid improvement not obtainable by any other method.

Professor EILE CURRIE said that his experience had been confined to eight selected cases. All the cases had done well, and the improvement had been so much more rapid and dramatic than was to be expected in cases of this type that he was unable to avoid the conclusion that sanoerysin was the favourable factor in each. These eight cases had impressed themselves on his mind more sharply than a far larger number of cases in which other recent methods had been tried. All the cases at first lost weight under treatment, and all experienced severe reactions at the beginning, but, on the other hand, the weight was rapidly regained after the inoculations, the cough diminished or disappeared, the sputum in several of the cases disappeared or showed a great fall in bacterial content, and some improvement was noticed in the x-ray picture. The use of serum was definitely helpful in the control of albuminuria, but it had its own inconveniences. He had found it useful to space the doses rather more widely than was originally advocated by Dr Secher during his visit to London in December last. The speaker believed that the use of sanoerysin should be safeguarded, not so much by reducing the dosage as by selecting patients with tuberculous lesions of relatively small extent. He thought that this treatment should not at present be handed over to general practice, but should be carried out by specialists at special hospitals.

SIR ROBERT PHILLIP said that the Medical Research Council was hard at work to determine whether, on the one hand, the experimental process advanced by Professor Moellgaard was sound, and, on the other, whether and to what extent the results brought forward could be corroborated by further results.

SATURDAY, JULY 11TH, 1925

## INTERNATIONAL RADIOLOGY

THE Congress of Radiology in London last week may be considered to mark the coming of age of radiology as a special department of medicine. It is true that it is thirty years since Roentgen made his discovery bringing to the point of utility a series of researches which had been prosecuted in a rather desultory way by physicists in this and other countries. But some few years elapsed before it was realized how great were the services the discovery might render to various arts, to none have they been so great as to medicine. The conference was not summoned as an International Congress, but it was attended by representatives of the specialty in many countries, who quickly voted with unanimity that it should be recognized as the first International Congress of Radiology.

If the Congress marked the coming of age of radiology, it was Sir Berkeley Moynihan who made the birthday speech in his Mackenzie Davidson Memorial Lecture which is published in full in the opening pages of this issue. That the lecture should have been delivered during the first International Congress of Radiology was most appropriate, for Davidson, then at Aberdeen, was one of the first to take up the new method seriously, to equip himself with the best apparatus available, and to be satisfied with nothing but the best results then possible to be obtained. Afterwards he removed to London, and, by his ingenuity in devising apparatus, his energy in trying new methods and the enthusiasm with which he preached the new doctrine, did in the early days more, perhaps, than anyone in this country to establish its practice on sound lines. The choice of the orator also was fortunate. Sir Berkeley Moynihan's powers of lucid exposition are unrivalled, and no surgeon of the future will be in quite so good a position to describe the greater accuracy of diagnosis which is owed to radiology, for he has watched its development and himself experienced the steady increase in the value of the information it can afford. Emphasis must be laid on the word 'can,' for, as he insists more than once, the radiologist must be allowed time enough for his study of the case if the full advantage of all that he can do for the surgeon is to be obtained. It will not do merely to direct that an x-ray examination must be made, the surgeon—or, for that matter the physician, whether doomed to be a surgeon or not—should consult with the radiologist. If this were always done it would prevent misunderstandings and would incidentally reduce the activities of the non-medical radiologist, a reform for which there is need. Emergencies apart, what the surgeon ought to say to the radiologist is "Examine this case thoroughly, using all the methods at your disposal, and then tell me and show me the evidence you have collected, giving me your judgement on its significance."

Sir Berkeley Moynihan confined his survey to the alimentary canal, going beyond it only to make a brief reference to the urinary tract. Even so, he had a very wide field from which to gather his harvest, and he brought in many sheaves, for, much as radiology has

done to make diagnosis more accurate in diseases and injuries of the head, the chest, and the limbs, it has done more, with the possible exception of the last named, for the abdomen. He did not stint his praise. Speaking of gastric diseases, with special reference to ulcer, he proclaimed that it was hardly too much to say that we owe almost everything to the radiologist, the accuracy of the radiologist in the diagnosis of gastric ulcer nearly approaches that of the surgeon who, with the abdomen open, inspects and handles the stomach. Of what used to be called idiopathic dilatation of the oesophagus, now known as cardio-sprism, we could, he said, "know nothing accurately apart from the examination made by the radiologist." Again, he observed that the recognition of diaphragmatic hernia "without the aid of radiology is excessively difficult or perhaps impossible." Passing to the diagnosis of diseases of the gall bladder, he said that in cholelithiasis radiology enables a diagnosis to be made which otherwise would be in doubt, it discovers associated lesions in neighbouring viscera, and is an instrument of research into the composition of stones, and may so throw light on their formation.

But, though he was generous in recognition Sir Berkeley Moynihan discussed quite frankly the limitations of radiology, directing attention in particular to gastric ulcer and cholelithiasis. His observations should be read in full, but a not unfair summary would be that a positive report from the radiologist is of far greater value than a negative, and that where a negative report is opposed to the impression produced on the mind of the surgeon by all the clinical evidence taken together it should be disregarded. Perhaps here we have light thrown on dark words he used at the beginning of the lecture when he described himself, not for the first time, as "a physician doomed to the practice of surgery." Others, perhaps, would gladly accept the doom without repining, but the phrase was something more than a jest. It meant, we suspect, that everyone must, before all things, strive for the highest attainable accuracy of diagnosis, and must neglect no means to that end before resorting to the knife—that the day of the "look and see" surgeon has passed. He was careful to insist that once the diagnosis has been made as precise as possible there should be no delay in acting upon it. This is one of the observations that make the lecture of so great value to the general practitioner. Before closing Sir Berkeley Moynihan spoke shortly of therapeutic applications of radiology, and referred to a method he has tried in carcinoma of the stomach—that of opening the abdomen and exposing the organ for forty minutes to x-rays under a single layer of macintosh gauze. In two cases in which this method was used the results proved decidedly encouraging for when the abdomen was opened again seven and nine weeks later the growths were so changed and shrunken that it was possible to remove them with all their attached glands. Reports of future experience with this method will be awaited with particular interest.

The verdict of all who attended it is that this first International Congress of Radiology was a great success. Foreign members praised the way in which it was organized; the credit is in large measure due to Dr Robert Knox, chairman of the Organizing Committee who was described by Mr Thurstan Holland at the dinner as the moving force behind the whole project, Dr Stanley Melville, secretary-general, and the joint secretaries, Dr Lynham and Dr Muir, upon whose shoulders, as secretary of the British Institute

of Radiology—the headquarters of the Congress—a great deal of the preparatory work fell.

The Congress was international, no nation was excluded, and twenty-two, we are told, were represented. It had several set discussions and saw some striking demonstrations, but the number of papers in the three sections was so large that time to debate them could not be found. Following our preliminary notice published last week, the work of the Congress is reported at some length in this issue (p. 67). The full text of all the papers will, we are told, eventually be published in the *Journal of Radiology*.

Before separating, the members decided by a unanimous vote that the next Congress shall be held in Sweden three years hence; it was to be noted at the dinner that no speaker was received with applause so warm as the leading representative of that country, Dr. Forssell, who seemed to personify for his brother radiologists the spirit of international amity the Congress was designed to promote.

### THE CIVIL RESEARCH COMMITTEE.

We gave last week (p. 25) some particulars of the Treasury minute defining the functions of the new Committee on Civil Research and of the Lord President of the Council's speech indicating the objects with which it has been set up. Lord Balfour described the new Committee as "an additional wheel required to complete the mechanism of Cabinet government," and he specified three directions in which the services of this new Committee would at once be available—namely, in co-ordinating the work of different Government departments, in tackling special problems, and in securing the counsel of the Dominions.

Health questions have suffered as much as, if not more than, other questions from our present ill-co-ordinated system of administration. Such problems as hookworm disease, sleeping sickness, yellow fever, plague, and bilharzia are international, and demand co-operation between neighbouring countries. It may be difficult to secure this co-operation if rival Governments must first be consulted, but within the British Empire co-operation should be possible of achievement. Nevertheless, our present system of administration offers insuperable difficulties, as all reformers in imperial hygiene know only too well. Thus, all medical problems in India are handled by the India Office, and those of Ceylon by the Colonial Office. Hence, under existing arrangements the much needed campaign against hookworm disease would be superintended by two separate organizations, each with its own traditions, and each jealous of any infringement of its rights. A traveller returning from a tour of the Empire would find it difficult to discover which Government department, if any, supervised the health questions which seemed to him so pressing in different parts of the Empire. The Foreign Office, the Colonial Office, the War Office, the Air Ministry, the Admiralty have each established areas of authority, the self-governing Dominions are, of course, entirely independent in such matters, so that the means they are taking to tackle their health problems come only unofficially to the notice of the central seat of government. In the face of such a complicated and unco-ordinated system, small wonder that no bold attempt is made to attack problems of imperial health.

Health matters are, we understand, among the first which the new Civil Research Committee proposes to study, and the particular question of co-ordinating

medical services throughout the Empire is worthy of the first claim on its attention. Its elastic nature should enable this Committee to cope with almost any question, for it would appear that the only permanent member of the Committee is the Prime Minister, though the Minister nominated by him to act as chairman will, it may be assumed, act in that capacity continuously for a considerable period, if not for the lifetime of the Ministry. For any particular subject to be discussed the chairman (or the Prime Minister) will call together a committee of experts. It may perhaps be assumed that there will be committees dealing with shipping, trade, foodstuffs, agricultural problems, mining and many other questions which require the co-ordination of different Government departments.

In its working the new Committee will not be hampered by rigid rules. The Treasury minute lays it down that the Civil Research Committee shall be an advisory committee without administrative or executive functions. Lord Balfour, in laying stress on this, said that it would be modelled on the Committee of Imperial Defence, which was established some twenty-five years ago to co-ordinate the work of the army and navy and to consider all questions connected with the defence of the realm. In referring to the advantages which flowed from the work of this body he remarked that a valuable characteristic of the Committee of Imperial Defence was that it could not give orders to anybody, instead of increasing friction between departments and causing jealousy against itself in the minds of departments, it was of inestimable value in making all the departments work as parts of one machine. We imagine, then, that health questions which have been discussed by the Civil Research Committee, often, probably, together with representatives from different Government departments and from the Dominions and Colonies, will be referred back by the Cabinet to the home departments concerned, and, if the Committee's deliberations have pointed to any practical measures, it will bring pressure to bear on each department to see that these are executed, and will satisfy itself that they are executed.

So far we have spoken only of the more efficient working of the machinery of State as already established, but we think we detect in the establishment of this advisory body something more than a touch of lubrication of the wheels of government. We hope we may discern beneath the argument of expediency official recognition of the principle that henceforth human life must be guided by science. Nearly all the necessities of life are brought to this small island from distant lands, and a watchful eye must scan the activities of far away fields. In our peculiarly vulnerable position foresight alone can protect us from dangers threatening ahead, and for this peering into the future we shall need the help of every instrument of science. The Civil Research Committee will, we hope, not only possess the seeing eye, but also the co-ordinating brain. Certainly we need both these faculties in all the big health problems of the Empire.

THE Royal College of Surgeons of England will give a reception at its house in Lincoln's Inn Fields on Monday evening, July 13th, in connexion with the Convention of English-speaking Ophthalmological Societies. Fellows and Members of the College wishing to attend are asked to apply to the Secretary of the College for cards of admission.

## AN EXHIBITION OF SPECIMENS

During the present month a special exhibition of specimens is to be seen in the museum of the Royal College of Surgeons of England, Lincoln's Inn Fields. The specimens shown represent additions and donations made during the past twelve months, and many of them are of exceptional interest. One hundred and seventy of these new specimens are of a pathological nature, and have a direct bearing on problems which are now occupying the attention of medical men. Especially numerous are the preparations which illustrate lesions of bone. The visitor's eye is at once attracted by a series which was presented to the College by the executors of the late Sir William MacEwen, and represent the results obtained by that great surgeon during his experimental inquiry on bone growth. Sir William often visited the museum of the College to study Huxleyan specimens, particularly those which illustrate the manner in which bones grow, and had expressed a wish that his own might be added to the Huxleyan series. A valuable addition to the same series is made by Mr. I. W. Hay Groves. It is evident from the number of specimens of myeloma in the neighbourhood of the knee-joint that this form of tumour is engaging the attention of surgeons. Visitors to the exhibition have an opportunity of satisfying their curiosity as to the nature of the ailment which so disfigured the face of a chimpanzee, known as "Mick," which lived in the ape house of the Zoological Gardens for twenty-seven years. His muzzle became massive, and two horn-like bony excrescences arose at each side of his nose—very similar to the condition seen in the "horned" men of West Africa, a condition now described as frambesial osteitis. The skull of "Jock," who was also in the Zoological Gardens for many years, is also exhibited, and shows a less marked degree of the same disorder, evidently one which results from some form of slow infection. A striking feature is the massive growth of the alveolar bone of the jaws, with an arrest in the eruption of the permanent teeth. The exhibition contains also some delicate dissections which illustrate points in the finer anatomy of the thyroid and other glands of internal secretion of lower vertebrates. For these Mr. R. H. Burne, physiological curator, is responsible. Of especial interest are the preparations which show the peculiar system of lymph vessels which are connected with the thyroid gland of *Lophius*, the angler fish. Many additions have been made to the craniological and other series in the museum. The exhibition is open to all medical men between the hours of 10 and 5, except Saturdays, when the museum closes at 1 o'clock.

## "GOUNDOU" HORNE MEN IN AFRICA

The nature of the osseous tumours involving the infra-orbital ridges of the maxillary bones in a case of the condition, referred to in the preceding paragraph as that presented by the horned men of West Africa, was described to the Royal Irish Academy by the late Professor Alexander Macalister in 1882 and 1883. In 1887 Surgeon J. J. Lempriere, of the Army Medical Staff, described in our columns three other cases of this condition, which is well known on the Gold Coast under the title of "henpige" or "dog's nose," and on the Ivory Coast as "n'goundou," from which its more common designation of "goundou" is derived. Other accounts of this disease were contributed to this JOURNAL by H. Strickland and J. O. Shucrore. Major Botreau-Roussel, of the French Colonial Army, has now published a book on "goundou," based on his observations on the

Ivory Coast between 1912 and 1917, when he collected 130 cases and operated on 113 patients. He claims to have established that this condition is only one symptom of an hypertrophic osteitis affecting several bones and sometimes involving the greater part of the skeleton. He maintains that it is always secondary to tropical frambesiosis. Professor Cornil of Nancy has shown that the lesions are not tumours in the pathological sense of the term, but are due to inflammatory osteogenic hyperplasia comparable with that occurring in syphilis. Dr. J. N. Roy of Montreal, who was associated with Major Botreau-Roussel in 1912, and has himself observed thirty-four cases, contributes an article to the *Revue de Laryngologie, d'Otologie et de Rhinologie*, in which he disagrees with the view that this condition is due to frambesiosis, or to a lesion of the central nervous system, or to syphilis, or to insect bites. Roy has found spheroidal bodies 25 to 30  $\mu$  in diameter in these tumours, and is of the opinion that etiological significance is to be attached to them. While admitting that goundou and yaws are often associated, Roy insists that there is no real connexion between the two diseases. Botreau-Roussel, however, in support of his contention points out that in 103 out of his 130 cases frambesiosis either accompanied or preceded the development of the osteitis. The bone lesions appearing in 98 cases during the eruption or immediately afterwards. He also emphasizes the importance of the fact that the pathological processes in the bones are similar to those in syphilis and frambesiosis. In one case the bone lesions and the skin eruption yielded simultaneously to treatment by novarsenobenzol. The disease is far more widespread than was originally believed, and Roy has collected evidence of its occurrence in the West African littoral, Zanzibar, British East Africa, the Malay Peninsula, the East and West Indies, Southern China, Honduras, Mexico, and Brazil. He mentions an instance of the disease being contracted by a European who had lived on the west coast of Africa for twelve years, and reports the discovery of a skull of a 7-year-old child, found in an Inca grave in Peru, which presented the typical aspects of the condition. The bony growths are usually bilateral, and develop on the nasal bones or on the ascending process of the superior maxilla. These bones may be invaded simultaneously. The disease may become generalized, exostoses forming on nearly all the skeletal bones. The disease occurs usually during early childhood, but is often observed in adults, and is possibly a little more common in males than in females. Botreau-Roussel illustrates his descriptions with a large number of photographs and radiographs, and appends a good bibliography.

## A RESEARCH INSTITUTE FOR KENYA

Not long before his tragic death at Nairobi last February the late Sir Robert Coryndon, Governor of the Colony, had expressed himself strongly as to the need for a museum and library devoted largely to the study of natural history and its allied sciences in Kenya Colony, a proposition that has met with the universal approval it deserves. It has been felt in the colony that the services of Sir Robert Coryndon were of the greatest value to Kenya, and it is proposed to build a memorial to him at Nairobi in the form of a hall or the wing of a building to bear his name and form part of a larger museum or institute for the advancement of the natural sciences on the progress of which the welfare of the colony depends. There is at present in Nairobi a small but admirable Natural History Museum, full of merit so far as its restricted resources have permitted its development and receiving some small measure of support from the public purse. It was Sir Robert Coryndon's idea that this museum should be enlarged and extended in connexion with a library and an institute for the undertaking of research, and he

<sup>1</sup> BRITISH MEDICAL JOURNAL, December 10th 1887 p. 1273

<sup>2</sup> Ibid. 1893 vol. 1 p. 163

<sup>3</sup> Ibid. 1910 vol. 1 p. 503

<sup>4</sup> *Osteites l'antiquité (Goundou)*. Par Botreau-Roussel. M. le Dr. Major de Ire Classe des Troupes Coloniales. Collection de la Société de Pathologie Exotique. Paris. Masson et Cie. 1925 (Roy. 8vo pp. 129 69 figures. Fr. 16)

particularly mentioned veterinary and botanical research as called for at the present time. An appeal was issued from Government House, Nairobi, last March, asking for subscriptions to the Corndon Memorial Fund, and this appeal has met with a considerable amount of support locally. It has now been brought to the attention of a wider public, and it may here and now be recommended to the notice of readers of the *BRITISH MEDICAL JOURNAL* as an appeal for funds for an object that is entirely deserving. Sir Robert Corndon had some five and thirty years of experience as an administrator in South Africa and Kenya Colony. He recognized that vast areas of fertile land in the African continent are closed to human enterprise by disease and by the insect carriers of disease that render them uninhabitable for working man and domestic beast alike. He knew that it is to science—bacteriological, entomological, veterinary, and so forth—that we must look for the key to these areas, if they are to be rendered fit for human habitation, whether black or white. To those interested in the population of tropical countries it has long been, indeed, a platitude that the man of science is even more indispensable to the administrator in the tropics than he is in less torrid climates. The fact is known, and, what is more, is acted upon nowadays by our politicians and our statesmen, and was emphasized only a week or two ago by Mr Oimsby-Gore when addressing the Imperial Entomological Conference. As was perhaps natural in the circumstances, Mr Oimsby-Gore eulogized the horn of the administrator in this partnership of government and science. So, too, does the writer of a leading article on "Science and administration" in the *Times* of June 20th, who describes the modern co-operation between statesman, entomologist, bacteriologist, botanist, veterinary surgeon, and medical man in the enterprise of tropical sanitation adding the words "But the part of the statesman is the greatest, because if he fails complete disaster is assured." It is always an ungrateful task to attempt to assess separately the values of the work performed by the hand and the head acting together, although we cannot help thinking that it has been done by some noted fabulist. At any rate, the teaching of experience shows that the plucking of a sleeper across the rails by a naughty child can assume complete disaster to the best train in the world.

#### THE SANITARY CONDITION OF BARGES

DURING recent years the annual reports of the Registrar-General for England and Wales have provided evidence of the unhealthiness of the occupation of barges and lightermen. Thus in the period covered by the three years 1910, 1911, and 1912 the comparative mortality figure was 1,102, which compares very badly with 790 for all occupied males, of 470 for the open-air occupation of farm labourer, and of 838 for what one might conceive to be the like occupation of fisherman. These facts are commented upon by Dr Dearden in that part of the annual report of the medical officer of health for the Port Sanitary Authority of Manchester which deals with the sanitary condition of ships (pp 39-52). He points out that although amongst bargemen and lightermen there is an excess of liability to fatal accidents, as shown by the mortality rate of 193 against the average one of 49, yet this is insufficient to explain the high mortality figure. Excessive liability to respiratory diseases, particularly pneumonia, is the cause of the high mortality of bargemen. The fisherman whose record shows the effect of a strenuous life equally with that of the bargee, is in a totally different class when respiratory diseases are taken into account. The liability of the bargee to die from phthisis is the same as that for all male workers, as the figures quoted in Dr Dearden's tables show, but these tables, which compare the mortality of bargemen, fishermen, farm labourers, and occupied and retired males, reveal

the fact that the mortality of bargemen from pneumonia is almost twice, and then mortality from bronchitis more than thrice, that of fishermen. The mortality of bargemen from respiratory disease of all sorts is more than twice that of fishermen, and three times that of farm labourers. The occupation of bargee is one that should be favourable to good health, since it is carried out in the open air and involves a considerable amount of muscular exercise, but Dr Dearden's investigations have convinced him that the real reason for this excessive mortality from respiratory disease is to be found in the evil influence of the housing conditions on these boats. On one occasion during the year under review a company was prosecuted by the health authority for a nuisance existing on a barge, the offence being dampness of cabin and bedding owing to rain water and river wash penetrating through the scuttle hatchway. The magistrate decided that no nuisance had been proved and dismissed the summons. This decision must discourage a firm policy of reform.

#### EPIDEMIC HICCUP

DURING recent years the occurrence of epidemics of hiccup have been reported from time to time, and the etiology of this condition has attracted considerable attention. Dr I. T. Cadham of Winnipeg has recently published an account<sup>1</sup> of the three Winnipeg epidemics in 1919, 1922, and 1924. In the first of these epidemics 1,000 cases were reported, the second was on a smaller scale, but in the third a record of 1,400 cases was obtained in a population of a quarter of a million. Each of these epidemics began early in November, reached its height by the beginning of December, and declined rapidly. The great majority of the patients were adults, and more than 90 per cent of the cases occurred in males, no evidence of any racial immunity was forthcoming. In the 1924 epidemic four patients reported that they had had a previous attack in 1919, and two other patients had had a previous attack in 1921. All agreed that the symptoms in the second attack were less severe than in the first, and each patient was cured within thirty-six hours, whereas the previous attacks had lasted more than three days. Cultures from the naso-pharyngeal secretion yielded a streptococcus resembling that isolated by Rosenow, to whose work in this connexion we referred on April 7th, 1923 (p 603). It was considered, however, that no definite etiological factor had been established, though bacteriological investigations are proceeding. Each epidemic was associated with an outbreak of a catarrhal infection of the influenza type, which, however, appeared two weeks later and occurred equally in both sexes. The relation of hiccup epidemics to encephalitis lethargica has been much discussed, in both conditions the difficulty of tracing infection is pronounced. Dr Cadham points out that the first epidemic of hiccup in Winnipeg, in 1919, coincided with the first epidemic of encephalitis in that city, there being 104 cases of encephalitis, with 25 deaths. During the milder epidemic of 1921, 31 cases of encephalitis were reported, and in the winter session of 1922-23 108 cases, though during that time no record was obtained of a single case of hiccup. Three cases of encephalitis during the 1919 epidemic began with hiccup, one patient in 1921 developed hiccup simultaneously with myeloma of the arms, legs, and abdomen, and during the 1924 epidemic one patient suffered from herpes zoster, hiccup, and lethargy, suggesting the existence of a lesion in the central nervous system. Dr W. R. Brain has recorded the case of a patient developing a mild form of encephalitis lethargica after suffering for a month from intermittent brief attacks of hiccup.<sup>2</sup> He suggests that hiccup is probably a myoclonus of the diaphragm, a view supported

<sup>1</sup> *Journ Amer Med Assoc* February 21st 1925 p 580

<sup>2</sup> *BRITISH MEDICAL JOURNAL* November 10th 1923 p 806

by Dr M J Chevis, who attributes to it a rheumatic etiology. Dr Cudham believes that myoclonic spasms of the rectus abdominis occurred more frequently in these cases than is generally recognized. A little light is thrown on the difficult problem of infection by Dr L Archer-Brown,<sup>2</sup> who describes the circumstances attending the onset of the disease in himself during an epidemic in Philadelphia. Other interesting characteristics of this disease are the intermittent character of the spasms, the mild neuritis frequently following hyperaesthesia of the scalp, face, and neck, the slow pulse, and the absence of pyrexia. Various remedies have been suggested, but their value is difficult to estimate. Sedative remedies, including chloroform and morphine preparations, are perhaps most generally used, and protein injections have been recommended, and benzyl benzoate has been found useful.

### THE SPAHLINGER TREATMENT

From Parliamentary reports (p. 89) will be found a very full account of the memorandum presented to the Parliamentary Medical Committee by five of its members who recently went to Switzerland to visit M Spahlinger's laboratory near Geneva. The members of the party acted on their own initiative, and the recommendations with which the memorandum concludes are, by request, omitted. The opinion of the committee appears to be divided upon the question whether any action should be taken by it on the memorandum. M Spahlinger is now in this country, and on July 7th met at the House of Commons the five medical members who had made the journey to Geneva. We are informed that an interview between him and Sir George Newman was then arranged for some day next week, and that the Ministry is likely to maintain the position it has taken up all along—namely, that it is willing to give a thorough test to the method provided an adequate supply of serums and antitoxins can be assured. Another interview is to take place between the five members of Parliament and M Spahlinger on Monday to hear from him whether he can assure supplies for the treatment in London of a considerable number, say 1,000, cases of tuberculosis. As will be seen, the memorandum states that the public can entertain no hope of securing treatment by the method at the present time, and that it will be useless for patients to apply. There is, we are told, again talk of an appeal to the public to contribute to a fund to aid M Spahlinger in the preparation of the materials.

### THE HONG KONG MEDICAL CONFERENCE

At the invitation and with the co-operation of the Hong-Kong and China Branch of the British Medical Association, the China Medical Missionary Association held its seventeenth biennial conference at Hong-Kong last January. Delegates attended from Great Britain, India, and America, and authorities in different branches of medicine and surgery addressed the conference. By a coincidence the two bodies which met in conference—the Branch and the association—took origin in the same year (1886). In the following year the Hong-Kong College of Medicine was founded, with Sir Patrick Manson as its first dean, and out of this college grew the university and its medical school. The latest issue to reach us of the *Caduceus* (the journal of the Hong-Kong University Medical Society) is a special number, containing an account of the proceedings in the various sections. The conference opened with a congregation of the university in the City Hall, at which His Excellency the Governor of Hong-Kong, as Chancellor of the University, presided, and conferred the honorary

degree of LL.D. upon Drs Philip Conslind, Henry Houghton, Edward Hume, and Ernest Mann. The President of the Branch, Dr G E Aubrey, welcomed the delegates on behalf of the British Medical Association, and read messages, including congratulatory scrolls from the Provisional Chief Executive of the Republic of China and the Vice-Minister of Foreign Affairs, Peking. The *Caduceus* prints English renderings of these picturesque Oriental salutations, the Vice-Minister's message ends thus: "At Hong-Kong learned doctors will come together. Without good physicians how can we sustain lives? The modern science is superior to the old as it is more exact. I want to see some wonderful results which will outshine the past and guide the future." So much interest was shown in the proceedings of the Section of Medicine that it was decided to spread the discussions over five sessions, some thirty papers were read and debated, and the bulk of these will appear in full in the *China Medical Journal*. Irregular fighting has been going on in various parts of China for some years past, and for that reason much prominence was given in the Surgical Section to the subject of war wounds. In the Section of Obstetrics and Gynaecology there were good attendances, and the general discussions, we learn, were short and snappy. In view of the importance of the trade exhibition to delegates from districts where they are wholly out of touch with modern appliances and drugs, the Great Hall of the University was set apart for this purpose. The prudence of this decision is shown by the statement that this hall "soon became the most popular rendezvous for those not engaged in sessions and committees." Altogether the conference seems to have been a great success.

### SOUTH AFRICAN MEDICAL CONGRESS

The twentieth South African Medical Congress, Pietermaritzburg, from July 6th to 11th, was opened by Sir John Dove-Wilson. The President (Dr D Campbell Watt) delivered his address on the same day. The work of the congress is divided into five sections. The members are meeting as a whole to hear the opening addresses on the subject for discussion in each section at 9 a.m., and subsequently the sections hold their separate sessions. The sectional discussions and their openers are as follows: Medicine, "Focal infection," Dr R L Gudwood; Surgery, "Treatment of carcinoma of the breast," Dr H A Moffat; Public Health, "The milk supply," Dr S J Clegg; Obstetrics and Gynaecology, "Caesarian and prevention of foetal death," Dr Lance Impey; Special Subjects Section, "The work of the laboratory in relation to the practice of medicine," Sir F Spencer Lister. Two business meetings of the congress are being held and the South African Committee of the British Medical Association meets on two of the mornings. There is a trade exhibition of drugs, instruments, and so forth, and at a public meeting in the Town Hall Dr T Shadick Higgins, M.O.H. Cape Town is giving a lecture on public health in relation to social welfare. During the week social entertainments of various kinds have been arranged, including a civic reception and a banquet. The honorary general secretary is Dr C G Kay Shup.

The next issue of the *BRITISH MEDICAL JOURNAL*, dated July 18th, will be a special commemorative number in connexion with the opening of the Association's New House by H.M. the King accompanied by Queen Mary, on Monday, July 13th, and the dedication and opening by the Archbishop of Canterbury of the Memorial Gates erected by the Association as a tribute to its members who fell in the war. Articles, letters, and information relating to other matters will for the most part be held over

# NINETY-THIRD ANNUAL MEETING

of the

# British Medical Association,

## BATH, 1925.

BATH ABBEY

June 6th, June 20th, and July 4th, 1925

**T**HE Annual Meeting of the British Medical Association will be held at Bath at the close of this month, under the presidency of Dr F. G. Thomson, physician to the Royal United Hospital, Bath, and consulting physician to the Royal Mineral Water Hospital. The Annual Representative Meeting will open in the Concert Hall of the Pump Room at Bath on Friday, July 17th. The statutory Annual General Meeting will be held on Tuesday afternoon, July 21st, in the Concert Hall and on the evening of the same day the new President will deliver his Address to the Association in the Palace Theatre. The twelve Sections, among which the scientific and clinical work of the meeting is being divided this year, will meet on the three following days, July 22nd, 23rd, and 24th. The list of Sections and sectional officers, together with the programme and time table and other announcements, were published in the SUPPLEMENT to the BRITISH MEDICAL JOURNAL of July 4th. On the last day of the meeting, Saturday July 25th, there will be excursions to places of interest in the neighbouring West Country, some of which are briefly described in the article printed below. Descriptive and historical articles on Bath have appeared in our issues of December 6th, 1924, and of

## PLACES OF INTEREST AROUND BATH.

BY

JOHN HATTON,

DIRECTOR OF THE HOT MINERAL BATHS

Bath lies in the midst of a beautiful district, exceptionally rich in places of varied interest. The combs of Somerset, the Wiltshire Downs, and the Cotswold country of Gloucestershire, with the range of the Mendips running out into the Bristol Channel, provide an unusual variety of scenery. Stonehenge, and Wells Cathedral, the busy port and university city of Bristol, and the tiny artists' village of Castle Combe, give it houses like Longleat and Badminton, and the Cheddar Caves—all the extremes of contrast in human effort in the provision of places for worship or dwelling.

These notes cannot cover all the places selected for excursions during the meeting of the British Medical Association at Bath, but it is hoped that they will give some idea of the wealth of interest and beauty to be found in the West country.

### WELLS

"The Cathedral Church of Wells," wrote Professor Freeman, "is the best example to be found in the whole world of a secular church, with its subordinate buildings. There

is no other place where you can see so many of the ancient buildings still standing, and still put to their own use."

In 909 the diocese of Wells was established by King Edward the Elder, the existing church, probably founded by King Ina of the West Saxons at the instigation of St. Aldhelm near the springs or wells which gave the place its name, served as the first cathedral. The first Norman bishop, Robert of Lewes, built a great new church, but, to an unusual degree, this massive Norman cathedral has dis-

appeared. About 1180 Bishop Reginald built or rebuilt the church and part of the present church may be said to be the work of this prelate.

In 1206 Jocelyn became bishop and it is to this great man that Wells owes its crowning glory, the West Front. Jocelyn and his brother Hugh (afterwards Bishop of Lincoln) were natives of Wells, and they loved their birthplace with an undying devotion. Hugh, who built much in Lincoln Cathedral, gave of his wealth to Wells, and Jocelyn spent all that he had upon the cathedral in which he had been canon during the episcopate of Reginald, whom he was to succeed on the bishop's stool. Old Fuller wrote, "The West Front of Wells is a masterpiece of art indeed. England affordeth not the like," and modern writers have endorsed his praise. At the top is a large niche, where was the figure of Our Lord seated in glory. Below are the twelve Apostles, St. Andrew, the patron of the church in the centre, beneath this is the resurrection course showing naked figures rising

Wells Cathedral West Front

from their graves, then come rows of saints, kings and queens, and curious biblical scenes, and a coronation of Our Lady over the main doorway. The statuary is generally agreed to be the finest collection of mediaeval statuary in England, and many of the individual figures compare favourably with the greatest masterpieces of Italy or France. In 1242, full of years and honour, the great bishop died. "God," says Fuller, "to square his great undertakings giving him a long life to his large heart."

The interest of Wells is by no means confined to the West Front. The North Porch, one of the oldest parts of the church, is a magnificent example of early work still retaining much of the Norman influence, in spite of rich undercut foliage and beautifully carved figures. The most striking feature of the interior is the curious arrangement of inverted arches built to support the great central tower. The beautiful Lady Chapel, like the side chapels, is of the Decorated period, the windows are filled with richly coloured old glass—almost all in fragments. The fourteenth century Jesse window in the choir, however, is perfect. It is a superb piece of work, probably the finest of its kind in England. One of the side chapels has recently been restored; it is the war memorial for the county of Somerset, and here is kept the beautifully illuminated Book of Remembrance containing the names of all the men of the county who gave their lives in the great war.

Before leaving the interior of the cathedral other remarkable features must be mentioned. The clock, with its little figures of knights in armour galloping wildly round at the stroke of the hour, and the unique series of carvings, full of vigour and humour, in the capitals of the piers. The Chapter House, approached by a great twisting stair, is one of the gems of English architecture. The cloisters are largely of Perpendicular work, with the library over the east wall, containing many books of extraordinary interest, including the greater part of Bishop Ken's library and many of the old book chains still hanging on the original bookcases. Near by is the mortared Bishop's Palace, entered by a drawbridge, the building itself an exquisite example of early thirteenth century domestic architecture. A great gateway, usually known as the Bishop's Lye, leads into the Market Place. On the north side of the cathedral is the Denbury, an almost perfect example of the fifteenth century house, overlooking the great Cathedral Green, which forms the ideal foreground for the West Front. Beyond, under the Choir Gate, is the Vicar's Close, a perfect street of fourteenth century houses, at the far end the little chapel of the Vicar's Choral, now used by the students of the Theological College.

#### GLASTONBURY ABBEY

Glastonbury Abbey, around which legend and mystery have gathered more thickly perhaps than around any other sacred spot in Britain, lies in Tennyson's

island valley of Avilion

Deep meadowed happy fair with orchard lawn,  
And bowery hollows crown'd with summer sea

Here at the foot of the Great Tor St. Joseph of Annathier first planted in these islands the Christian faith, and the Chapel of St. Mary, more usually known as St. Joseph's Chapel, is the traditional spot upon which St. Joseph and his little band erected the original wattled church. It has been said that this was not only the first Christian church in England but the first in the world. To this spot, the legends tell us, was brought the Holy Grail. Tennyson not only records the story of the Holy Grail itself and the foundation of the Abbey, but of the famous Glastonbury thorn which still blossoms every year at Christmas tide. The most striking feature of the chapel is the beautiful Norman doorway with its richly ornamented niches adorned with sculptures.

The Abbey Church was cruciform in shape and over 550 feet in length. Still standing are three bays of the south nave aisle, the eastern piers of the central tower, part of the transept wings, one of the chapels of the northern transept, and the south wall with five pointed windows.

The discovery of the foundations of the Edgar Chapel has formed the subject of a book of unusual interest, *The Gate of Remembrance*, by Mr. F. B. Bond, F.R.I.B.A., who carried out the work of excavation. Tradition has it that the bodies of St. Joseph of Annathier, King Arthur, Queen Guinevere, and St. Patrick lie within the sacred ruins of this great Benedictine Abbey. It is curious that the best preserved fragment of this great group of religious

buildings should be the Abbot's Kitchen. This, like the Abbey itself, has now been acquired by the National Council, control being in the hands of a committee of trustees. The fourteenth century Abbot's kitchen is to be used as a museum for the many energetic tiles and numerous relics found in the course of the excavations.

The tower on the summit of Glastonbury Tor is all that remains of the fourteenth century Pilgrim Chapel of St. Michael. The view from the top of the Tor will find amongst the most beautiful and extensive in the county. In the High Street of the little town the fifteenth century Abbot's hostelry, now the George Hotel, will be noticed and a small building known as the Tribunal, which was originally the Abbot's justice room. Near the entrance to the Abbey precincts is the Glastonbury Museum, containing what is probably one of the finest collections of La Vieille objects in this country. The Lake Villages at Glastonbury and Merie have been systematically investigated by Dr. Arthur Bulleid, F.S.A., and Mr. H. St. George Gray of Trunton Castle, and the work, which is being resumed this summer, has yielded much harvest of finds of extraordinary interest.

#### CHEDDAR

The limestone range of the Mendips runs from the neighbourhood of Bath out into the Bristol Channel, where outliers appear as the Steep and Flat Holme islets. The tableland itself is generally bare, but by no means uninteresting, and the slopes and numerous combs are often of great beauty. The most striking scenery is, of course, in Cheddar Gorge, the finest limestone chasm in the county. Cliffs, crowned with pinnacles, rising in some places to a height of over 400 feet, stand sheer above the winding roadway, clothed with ivy and wild flowers, and inhabited by innumerable jackdaws and other birds. It is now generally agreed that the gorge has been formed by the action of water, it was at first a great cave, or perhaps a series of caves, cut by an underground river, the roof eventually falling in, leaving the open gorge. At the foot of the gorge are the famous caves. Gough's, the larger and more impressive, contains massive stalactite formations of wonderful form. Cox's Cave is smaller, but exquisitely fairy-like in its stalactite beauty. In the village is a restored Market Cross and the Perpendicular church of St. Andrew.

#### BRADFORD-ON-AVON

Some nine miles from Bath, at the other end of the beautiful Limpley Stoke Valley through which run the river, the railway, and the road, is Bradford-on-Avon, a picturesque little cloth weaving town disposed in terraces of sixteenth and seventeenth century houses on the steep hillsides. Rubber factories have taken the place of the cloth mills which once produced the famous West of England broadcloth, the successors of the hand looms brought to Bradford by the Dutch weavers in the seventeenth century.

The Saxon Church of St. Lawrence, one of the most perfect and precious of Saxon relics still existing, appears to have been built about the end of the tenth century, replacing the original wooden church built by St. Adhelm in the opening years of the eleventh century. For ages this little stone church, which consists of a chancel, nave, and porch, was lost to view, being almost obscured by various excrescences which had grown about the building in the course of its misuse as a dwelling-place and workshops, and it was not until 1857, when the vicar, Canon Jones, a local antiquary looking down on the town from the hill, was struck with what would appear to be a cruciform roof, which seemed to indicate the presence of something more important than ordinary houses. The bridge is another notable feature of Bradford-on-Avon, with a Mass chapel corbelled out on one of the piers. These bridge chapels are now extremely rare in this country.

Bradford has a notable example of fourteenth century work in the great Tie-Barn, attached to the Barton Farm. This huge barn (shown in Mr. Gerard's wood engraving)

is 167½ feet long by 30 feet wide, with an Early English roof supported by huge trusses carried direct from the ground. The Hall, formerly Kingston House, was built in the seventeenth century by John Hall, a wealthy cloth merchant of the town. The handsome front of the house, rich in decoration of the Jacobean style, is set on a terrace overlooking a particularly beautiful old English garden. The British Pavilion of the Paris Exhibition of 1900 was modelled on this house as being a typical example of an English country house.

This corner of Wiltshire is distinguished for the many fine manor houses it contains. Two of exceptional beauty and interest, Great Chalfield and South Wraxall, lie in the neighbourhood of Bradford.

#### Farleigh Castle

This picturesque castle ruin, lately much preserved by the Office of Works, dates from the reign of Richard II, when Sir Thomas Hungerford started to build. The gatehouse remains and the chapel, and in a ruinous condition two of the minor towers. The chapel contains several Hungerford monuments and much interesting armour.

#### Downside Abbey

The great and growing Benedictine Abbey of Downside is on the way to becoming one of the really important modern Gothic buildings in this country. Of the Abbey Church itself much still remains to be done, but the nave which is to form the memorial of the old Downside boys who were killed in the great war, is to be consecrated on July 25th, a couple of days after the excursion to Downside in connexion with the British Medical Association. In the north transept is the shrine of Blessed Oliver Plunkett, Archbishop of Armagh, who was martyred in 1681. Attached to the community is the well known public school of Downside, which was founded at Douai about the year 1605. It was removed to this country at the time of the French Revolution, and after being carried on for twenty years at Acton Burnell, near Shrewsbury, was established at Downside in 1914.

#### Norton St Philip

At this little village the chief feature of interest is the half timbered George Inn, an unusually well preserved specimen of a fifteenth century hostelry. The galleries overlooking the small courtyard are still in existence, and a winding stair leads to the great room at the top of the house, formerly used as a wool market. The Duke of Monmouth made this his headquarters on the night preceding the engagement of Philip's Norton, a short time before the decisive battle of Sedgemoor.

#### Lacock Abbey

An interesting example of a conventual establishment, Lacock Abbey, still preserves sufficient of the Augustinian nunnery, founded in 1232, to give a very clear idea of the life of a religious house in the Middle Ages. Later work has from time to time been added, much of it extremely beautiful, and the Long Gallery and some of the other rooms contain many interesting pictures.

It was at Lacock that Fox Talbot, an ancestor of the present owner and one of the discoverers of photography, made his early experiments and succeeded in securing photographic reproductions.

#### Corsham Court

Corsham Court, the seat of Field Marshal Lord Metchum, is a handsome Elizabethan mansion built about 1502. The

gallery contains an exceptionally fine collection of Dutch and Flemish painting. Near the entrance to the parlour are some beautiful dishouses founded by Lady Hungerford in 1668.

#### Longleat

Longleat the seat of the Marquess of Bath, K.G., described by Macaulay as 'the most magnificent country house in England, is situated in Wiltshire, but a small portion of the park lies in Somerset. The building was started in 1567 by Sir John Thynne, an ancestor of the present owner, and the design is in the characteristic sixteenth century style in which Italian influence is prominent. The beautiful park of 2,000 acres contains a large herd of deer. The lake is fed by the Longleat from which the place gets its name. The finest viewpoint is justly known as Heaven's Gate. When the saintly Bishop Ken was deprived of his see he was welcomed to Longleat, and there he wrote those well known morning and evening hymns: 'Awake my soul, and with the sun, and glory to Thee, my God, this night.' The Bishop was buried at Frome, where his grave may be seen at the east end of the beautiful St John's Church.

Tithe Barn interior Bradford on Avon (From a wood engraving by Horace Gerrard)

#### Bristol

Eleven miles from Bath, where the Avon is still navigable from the sea by outgoing steamers, is the great port and commercial city of Bristol. The city has a population of 350,000 and an unusual variety of industries, including world famous tobacco and chocolate factories and aeroplane works. The early history of Bristol and its strongly fortified castle is full of interest, but there is only space in these notes to refer to some of the most important features of the city as it is to-day.

As befits a city whence John and Sebastian Cabot sailed to discover the American continent, Bristol is primarily a port, and in the midst of its busy streets, and almost under the cathedral walls, there is still a suggestion of the Merchant Venturers of other days in the sight of a tall ship lying alongside the modern steamers at the city quays.

But the size of modern ships has rendered vast new docks nearer the mouth of the river necessary, and the corporation has spent over seven million pounds in the establishment of Avonmouth, where the largest of the docks has an entrance lock of 875 feet, and a depth of water over the sill of 35 to 45 feet in ordinary tides. Vast cold stores, grain docks, grain elevators, and warehouses and discharging stations enable the ever-increasing trade in grain, meat, timber, and oil to be dealt with expeditiously. The fruit traffic and the passenger traffic, especially to the West Indies, New Zealand, and Canada, are extending every year.

Bristol Cathedral contains much of interest, its most striking feature perhaps being the fine Norman doorway. It was originally the church of an abbey of Augustinian monks. Founded in 1142, there appears to be little doubt that an earlier church stood on the site. The vestibule to the Chapter House is very beautiful, and the graceful Early English Lady Chapel is of particular interest. It has some good examples of Early English, Decorated, and Perpendicular styles of architecture, and underwent extensive restoration in 1860-61.

Bristol also possesses in St Mary Redcliffe Church what is generally admitted to be the finest parish church in England. This exquisite building—

‘This mystery of a human hand,  
The pride of Limestone and the Western land’—

with its graceful spire, claimed by many to be the finest example of Perpendicular architecture in England, was largely built in the fourteenth and fifteenth centuries by the Cringes, two of the most famous of Bristol's Merchant Venturers. It was in the monument room in the tower that the boy poet Chatterton claimed to have discovered the Rowley manuscripts.

Bristol owes much to the munificence of the Wills family, and amongst the monuments of their generosity is a very fine Municipal Art Gallery. Isolated with the gallery is an unusually complete museum, which, by the way, is about to be further extended through the same generous hand. The geological department, the Drane Family Smyth botanical room, the Greville-Smith insect room, and the section illustrating the history of the city, containing much Bristol elf and Nilsen glass, are all of exceptional interest.

Bristol University is rapidly making history. It was only erected by a charter of King Edward VII sixteen years ago, and it already possesses the finest buildings of any modern university in Britain. Last month His Majesty the King opened the magnificent new block, given, at a cost of over half a million pounds, by Sir George Wills and his late brother, Mr H. H. Wills. (A description of the building and the opening ceremony appeared in the *BRITISH MEDICAL JOURNAL* of June 13th, 1925, p. 1098.) The most striking feature of this block is the University Tower, a truly magnificent piece of modern Gothic architecture. Rising to a height of over 200 feet, it is visible from many parts of the city. The belfry contains a great 10-ton bell, which has been christened Great George. The entrance hall beneath the tower contains some fine fan vaulting and a flight of stone steps leading to the Great Hall, of which the hammer-beam roof of English oak is a notable feature. The Faculty of Arts is housed in this building, the buildings erected for the Faculties of Science and Medicine are behind, and the Faculty of Engineering is housed at the Merchant Venturers' College. A new building on St Michael's Hill is now being erected for the Department of Physics. Next at hand are the Victoria Rooms, now the clubrooms and hall for the University of Bristol Union. Research work in fruit-growing is carried on at the University orchards at Long Ashton. The well known public school, Clifton College, is near by.

Bristol has many other features of interest. The Clifton Downs, on which stands the Cabot Tower, whence a superb view is obtained of the city and surrounding country, the magnificent Avon Gorge, spanned by the Suspension Bridge, a well stocked Zoological Garden, the Royal West of England Academy, at which educational work is carried on and an important annual exhibition held, and the Royal Colonial Institute, an active centre for visitors from the distant countries of the Empire.

One of the most notable of the old buildings of Bristol is the Red Lodge, a mansion built by the wealthy merchant Sir John Young in 1590. The Red Lodge has a handsome staircase and a magnificent carved chamber on the first floor. The whole building, full of objects of extreme interest, is in the care of the Bristol Savages, a club of artists and others interested in art generally.

Bristol possesses two large well equipped hospitals—the Royal Infirmary and the General Hospital—as well as a number of special hospitals.

of Bristol

## THE STATE OF THE PUBLIC HEALTH.

SIR GEORGE NEWMAN'S REPORT FOR 1924  
ENGLAND AND WALES

[First Notice]

THE annual report of the Chief Medical Officer of the Ministry of Health for 1924 has been issued. It deals with England and Wales, and the statistics it contains are founded on the returns published by the Registrar General relating to births, deaths, and infectious diseases, and on the various data and records in respect of vital data under the National Health Insurance Acts, supplemented by annual and special reports of medical officers of health, and from the results of investigations by medical officers of the Ministry and other departments interested in the physical, industrial, and social welfare of the people.

The report contains twelve chapters, and follows the general lines of its five predecessors, but in one chapter the administration of the Insurance Medical Service has been dealt with more fully than usual. To this we hope to return later. We may note at once that Sir George Newman again points out that the work is done quietly, without ostentation, with scant public recognition, often without thanks or reward other than the consciousness of work well done. The types of the few become conspicuous, the great volume of valuable work done by the vast majority passes unnoticed.

### Births and Deaths

In 1924 there were 28,198 fewer births and 28,450 more deaths than in 1923. The birth rate was 18.8 per 1,000 of population, a decline of 0.9 on the previous year and of 6.7 as compared with 1920. The death rate was 12.2 per 1,000 persons living, which is 0.6 higher than in the previous year but among the lowest in the history of the country. The decline in the death rate has been accompanied by a steady reduction in the birth rate from an average of 21.8 per 1,000 persons living in the decennium 1911-20 to 18.8 in the year 1924. With the exception of the war years the birth rate in 1924 was the lowest yet recorded. Sir George Newman considers it highly probable that the crude mortality rate is now at or near its lowest point and will hereafter increase, owing to the change in the distribution of age groups of the population. A declining birth rate, he points out, implies an increase of the average age of population, not necessarily any strengthening of the forces of mortality.

The diseases to which the most noteworthy increases in deaths were attributed are set out in the following table.

	Per 1,000 deaths
Bronchitis, pneumonia, and other respiratory diseases	174
Diseases of heart and circulation	168
Cancer and malignant disease	106
Diseases of the nervous system	100
All forms of tuberculosis	87

### Infant Mortality

Ignoring for the present the effect of illegitimacy, the infant mortality shows an increase over 1923 at all periods of the first year of life. It is pointed out that a high infant mortality rate implies (a) the loss of many infants, (b) the maiming of many surviving children, for conditions which kill some injure others, (c) a high death rate in the next four years of child life, and (d) the existence of unhealthy conditions in the mothers or in the home life of the people. The infant mortality was 75 per 1,000 births. Calculated on the average infant mortality of 1901-10, there was in 1924 a saving of 39,000 infant lives. It implies a better physical condition in children from 1 to 5 years of age, and a more enlightened understanding of personal and public hygiene. What is described as the "closely related mortality among women in childbirth" still remains high, and has shown little or no improvement since 1894. The number of women who died in childbirth was 2,703, and 144 died from conditions associated with it. Of the 2,847 as many as 1,018 died from puerperal fever—"a preventable condition."

<sup>1</sup> *The State of the Public Health*. Annual Report of the Chief Medical Officer of the Ministry of Health for the Year 1924. H.M. Stationery Office (Med. Soc. pp. 256 3 6d net).

In commenting on the statistics Sir George Newman points out that the relative slightness of the decline of mortality in the first month of life is consistent with the belief that neglect of ante-natal hygiene has had all consequences, but that the fact that some improvement, even in the first month of life, has been achieved is of hopeful augury. The evidence, he states, appears to show that whether or not some biological change is taking place in the reduction of virulence of certain maladies and infectious affecting children under 1 year of age, the predominant factor in the recent improved health of infancy is to be found in better mothering, proper food, and improved domestic conditions immediately concerned with child welfare. He warns us, however, against false confidence. International comparisons and other observations show that the problem is very complicated, and it is vain to argue that any one hygienic measure is sufficient wholly to account for the movement of the rate of mortality. Sir George Newman writes:

'When an historian says that the average citizen of 1925 is more civilized than the average citizen of 1725 he is making a general statement dependent upon a multitude of interrelated particulars and nobody is foolish enough to attribute the change to any one difference to say that man is more civilized now because such and such particular changes have come about. Unfortunately in medical history this particularism is ever and again repeated. We read that in such or such a town infant mortality began to decline when an infant welfare centre was established; therefore the welfare centre caused the decline. We have not long to wait before another particularist publishes the statistics of another town where infant mortality declined without the establishment of a welfare centre, therefore welfare centres are valueless. Both conclusions are worthless in logic yet both are triumphantly paraded by the sectaries to which they appeal. The lessons which other students of social evolution learned long ago—the lesson of the multiplicity of causation, is one that cannot be too often or too strongly impressed upon the student of communal hygiene. The history of infant mortality affords many instances of its truth.'

#### Small-pox

The second section of the report deals with general epidemiology, and special attention is directed to the serious increase in the group of epidemic diseases of the central nervous system—poliomyelitis, poliomyelitis, encephalitis lethargica—to the recrudescence of influenza in the early part of the year, and to the continued increase in the prevalence of small-pox. The net total number of cases of small-pox notified in England (there were none in Wales) during 1924 (after revision of diagnosis) was 3,797, as compared with 2,504 in 1923. Eight cases were notified and verified in port sanitary districts. The number of deaths was 8, including one port case. A table is given showing that from 1911 to 1917 the number of cases diminished, but that from that year onward the number has increased: there were 7 in 1917, and 3,797 in 1924. In the first four months of 1925 the number (as yet unreviewed) was 2,214, with 3 deaths. The regional distribution was irregular. In London there were only 4 cases, in Derbyshire there were 1,351, in the North Riding of Yorkshire 539, in Nottinghamshire 536, in Northumberland 401, in Cumberland 186. Altogether, excluding the port sanitary districts, small-pox occurred in 119 out of a total of 169 sanitary ports in England. The general character of the disease since it began to increase in England has been mild and the mortality low. The occurrence of small-pox of a mild type has been a frequent feature in the history of the disease. Sir George Newman examines the suggestion that the mild type should be distinguished from true small-pox and given a separate name. He does not accept this view, and observes that the sound principle is "that notifiable specific disease should be notified as such, whether the attack be severe or mild," and whether it be scarlet fever, enteric fever, diphtheria, encephalitis lethargica, or small-pox. "or the control of small-pox the chief need is eradication, and, he says, "successful vaccination and re-vaccination constitute the only efficient protection against small-pox whether of the mild or severe form," he states further "that though early diagnosis, prompt isolation of small-pox patients in suitable hospitals, effective disinfection, supervision of 'contacts,' and other such public health methods are invaluable they are no substitute for vaccination."

(To be continued.)

## Scotland.

### EXTENSION OF ANTE-NATAL CLINICS IN EDINBURGH

At a meeting of the directors of the Edinburgh Royal Maternity and Simpson Memorial Hospital on June 26th it was intimated that the great popularity of the welfare clinics for mothers and children organized by the hospital had made it necessary for the directors to require additional accommodation. The pressure on the outpatient department had in recent months been very great and the clinics, which were at first held twice a week, were now open on five days a week. The total number of visits to the clinic had increased from 2,444 in 1920 to 6,073 in 1924. An adjoining house had been bought and was in process of being adapted for the purpose of the clinics, and when this was complete it was hoped that the department would be worthy adjunct to the Royal Maternity Hospital, which had been the pioneer institution in establishing clinics for the expectant mother.

### ROYAL (DIET) VETERINARY COLLEGE, EDINBURGH

Sir Robert Greig, chairman of the Board of Agriculture for Scotland, distributed on July 1st the prizes at the Royal (Diet) Veterinary College, Edinburgh. Professor Hudson Beve, chairman of the board of governors, who presided, said that the college had been for some years in occupation of its present premises, but until recently, owing to lack of money, the fittings had been deficient. All the laboratories, classrooms, and lecture rooms were, however, now being fitted. The board of governors was making arrangements for an official opening in October, and he had no doubt that next session the amenities of the college would be vastly improved. It was hoped that it might in future rely upon the generosity of some of the wealthier citizens of Scotland to endow the college. Research was urgently needed in many directions—for example, in connexion with animal breeding and diseases and for improvement of the livestock. Sir Robert Greig, in his address to the students, said that if they expected to make a fortune out of their profession he feared they would be disappointed, but if they wanted a profession in which they could feel sure that they could put a great deal into their life, then they had been fortunate in their choice. More and more their profession was linking up with the medical profession, more and more preventive medicine involved the veterinary profession, and more and more did comparative pathology and physiology throw light upon human disease. In the last few years several institutions devoted to the study of the physiology and nutrition of animals had arisen in Scotland, and there were now more appointments for first-class investigators than there were first-class investigators to fill them. The public services of the veterinary profession became more extensive every year, and a further important extension would be brought about by the Milk and Dairies Acts which came into operation on September 1st next. He looked forward to still greater development of the status and usefulness of the veterinary profession.

### ROYAL SANITARY INSTITUTE CONGRESS

The thirty-sixth congress and health exhibition at the Royal Sanitary Institute, which is to be held at Edinburgh from July 20th to 25th under the presidency of Sir John Gilmour, the Secretary for Scotland, will be attended by more than 800 delegates from public health bodies, departments of home and Dominion Governments, and representatives from foreign countries, including the United States, France, China, and Japan. The congress is divided into five sections—namely, sanitary science, under the presidency of Sir George Newman, engineering and architecture, maternity and child welfare, personal and domestic hygiene and industrial hygiene, under the presidency of Dr. W. E. Elliot, Parliamentary Under-Secretary of Health for Scotland. During the congress various conferences have been arranged for representatives of sanitary authorities, medical officers of health, engineers and surveyors, veterinary inspectors, and health visitors. The Lord Provost of Edinburgh will hold a reception for the

members and delegates on July 20th, and lectures to the congress will be delivered by Sir Leslie Mackenzie and Dr Charles Porter. In connexion with the congress a health exhibition will be held in the Waverley Market.

#### SCOTTISH OPTICIANS AND MEDICAL BENEFIT

At a meeting of the 1st of Scotland Branch of the British Optical Association on June 23rd the question of optical benefits under national health insurance was discussed. Mr Archibald Young presided, and a resolution was unanimously passed that the association should protest against the recommendations issued by the Insurance Department of the Ministry of Health in taking away the right of insured persons to consult opticians when needing glasses, and requiring instead the production of a medical certificate before a claim for optical treatment could be accepted by an approved society. In support of this resolution it was urged that the recommendations of the Insurance Department of the Ministry of Health were absurd, because of the inability of the general medical practitioner to estimate the refraction of the eye, and that they were extravagant because of the expense to approved societies if, as was suggested, insured persons from all over Scotland should be required to travel to one or other of the few centres where properly qualified ophthalmic medical practitioners or hospitals were to be found.

## Ireland.

#### ROYAL MEDICAL BENEFICENT FUND SOCIETY OF IRELAND

In submitting the eighty-third annual report of the Royal Medical Benevolent Fund Society of Ireland the central committee states the number of grants awarded during the year was 86, an increase of 3 as compared with the preceding year. Of these 5 were made to medical men, 8 to orphans, and 73 to widows. The amount disbursed in grants was £1,755, as compared with £1,540 in 1923-24. The average amount of the grants has thus increased from £18 10s 7d in the former year to £20 8s in that now under review. In presenting the audited balance sheets of the general fund and of the Osborne fund the committee once again wishes to express its thanks to the honorary secretaries of the branches for their work, and to the individual subscribers for their support. The income of the general fund from all sources amounted to £2,097 1s 6d. In this is included the sum of £422 15s 10d, the amount of income tax refunded for two years, the receipts under this heading during the current year will be only about half of that amount. Dividends and interest yielded an increase of income of £48 19s 2d. Subscriptions paid through branches, including those of the Dublin area, show an increase of £21 9s 6d, while those paid through the central treasurer have increased by £20 5s. The British Medical Association is thanked for collecting £26 13s. Donations amounted to £21 10s, being a life-membership payment of £10 10s by the President of the Royal College of Surgeons, Mr R C B Maunsell, and £11, the "Thankoffering of a Widow" who at a time of dire need received a special grant from the fund. The Irish Medical Association sent £20 and the Dublin Clinical Club £5 5s. No legacies were received during the year, nor was any addition made to the invested capital of the fund. At the beginning of the year the Osborne fund stood indebted to the general fund to the amount of £220 18s 5d. On June 18th, 1924, the central committee, having reviewed the position, resolved to suspend charges on the Osborne fund until such time as it showed a credit balance. In accordance with this resolution all grants have been charged to the general fund, and at April 30th, 1925, the indebtedness of the Osborne fund had been reduced to £109 12s 8d. Looking to the future, there are some factors which cause the central committee anxiety. There has been a fall in the capital value of railway stocks, and the matter has been submitted to the trustees for consideration and such action as they deem fit. The country is passing through a period of financial stress, and in common with all classes of the community medical men have suffered, and that the subscription

list has shown some increase is felt to be a matter for congratulation. Those who subscribe do so generously and merit thanks, but the committee asks for the support of the many who have not hitherto helped the fund, to enable it to bring relief to those connected with the profession in Ireland who come to it in their time of need. Only by widening the field of support can the fund be maintained on a sound financial basis.

## England and Wales.

#### ROYAL NATIONAL SANATORIUM, BOURNEMOUTH

VISCOUNT HAMBLETON, who has been elected president of the Royal National Sanatorium, Bournemouth, of which he had for many years been treasurer, presided over the annual meeting, when it was mentioned that the institution had been in existence for seventy years, and that Bournemouth was selected as the place at which it should be established after very full inquiries. The annual report submitted by Dr F G Penrose stated that 97 patients were in the institution on January 1st, 1924, that 350 (164 men and 186 women) were admitted during the year, that 342 (158 men and 184 women) had been discharged during the year, and that there had been 16 deaths. The daily average number of patients under treatment for the year was 94. A considerable number of patients when discharged were fit to resume their occupations with a reasonable expectation of permanent benefit from the treatment received. The financial position was satisfactory—the total ordinary income amounting to £11,555, and the ordinary expenditure to £10,163. A legacy had been bequeathed by Miss Julia Thomas to cover the expenses of the free treatment of poor patients who for a year previously had usually resided in the County of London. At the request of the Ministry of Health the charge for the treatment and maintenance of patients sent by local authorities had been reduced from £2 5s 6d to £2 3s a week, and this would thus reduce proportionately the annual income received from this source. A vote of thanks to the committee was passed on the motion of Mr F G Lefroy, seconded by Dr Hila Greaves, and the chairman then proposed a vote of thanks to the medical, surgical, and dental staffs, which was carried by acclamation. After a vote of thanks had been passed to the chairman those present made an inspection of the institution.

#### THE MIDDLESEX HOSPITAL

Mr T R Feens of Hull has presented £20,000 to the medical school of the Middlesex Hospital to provide an institute of otology, with special facilities for research in connexion with the ear, nose, and throat. It is proposed at first to install the institute on the top floor of the reconstructed buildings in Cleveland Street, where patients are to be housed during the rebuilding of the hospital. A laboratory, museum, and library will be established, and facilities will be given for post-graduate and otological study and research. It is possible that studentships will be endowed subsequently if further financial support is obtained. The institute will enable post-graduate students from America and the Dominions to complete their studies in London, and English students will no longer find it necessary to visit the Continent for such work.

#### TRAINING OF HEALTH VISITORS

We referred on February 21st, 1925 (p. 384), to a memorandum (101/M C W) issued by the Ministry of Health detailing the conditions on which grants for the training of health visitors will be given, and stating that, as a condition of the payment of grant, students who take either of the courses of training specified in the memorandum will be required to enter for an examination to be conducted by a central examining body approved by the Minister for this purpose. The Minister has now approved the Royal Sanitary Institute as the central examining body to conduct the examinations for health visitors in accordance with the conditions prescribed in the memorandum, and to issue health visitor's

then functional position, and at the request of the Commission I give them my opinion (which they adopted) as to the best way of carrying it out.

I had no intention of occupying your columns by a discussion on the merits of this question. The college has always been perfectly ready to discuss them. They were fully before the meeting of the court of governors of the college last month, and not a voice was raised in favour of separation. My only object was to point out certain apparent misconceptions as to the present position of the question—I am, etc.,

Capetulo Penmaenmawr, July 6th

ISAIAH OWEN

### REVERSE PERISTALSIS

SIR,—Cases like that described by Dr R E Lord (BRITISH MEDICAL JOURNAL, July 4th, p 13) are still discredited by many doctors, and even by many Roentgen-ray specialists. What the latter describe as "antiperistalsis" is something very much less in degree than the vomiting of formed faeces which have been passed upwards from the colon—probably from the descending colon—by reversed peristalsis, through the ileo-caecal valve (or what represents it) and the pylorus. I have taken considerable interest in the subject, especially since 1904, when I wrote a paper entitled "Faecal vomiting and reversed peristalsis in a functional nervous case." One of my conclusions then was

"Vomiting of formed faeces in the absence of malingering and gastro-colic fistula, practically only occurs in functional nervous cases. This may partly be accounted for by remembering that antiperistalsis, if it occurs at all, is likely to be more foreboding when the muscular walls of the gut have not been previously weakened by overdistension or gross organic disease."

I now believe that vomiting of formed faeces does not occur in cases of gastro-colic fistula. Malingering (that is, the swallowing of formed faeces and then vomiting them up again) can hardly ever be seriously entertained as an explanation. It appears also that vomiting of formed faeces (actual scybala) never occurs in any case of gross organic intestinal disease, but I would not now like to say that the presence of nervous disease (whether functional or not) is necessary for its occurrence. Surely, all cases of severe constipation in which relief, with vomiting, is obtained by the use of enemata suggest that antiperistalsis is called into play—I am, etc.,

F PARKES WEBER

London, W 1, July 4th.

### RAW PANCREAS BY THE MOUTH IN THE TREATMENT OF DIABETES

SIR,—May I add the following experiment to that published in your issue of June 13th, to show that fresh raw pancreas by the mouth is useless in the treatment of any type of diabetes? Drs Harrison, Graham, and myself proved that raw pancreas is no substitute for insulin, a point which our opponents admit. But then claim that it is beneficial in non-insulin cases is apparently still maintained. The following two cases showed no benefit at all from raw pancreas by the mouth.

Case A, a woman aged 48, is a mild obese diabetic. Case B a woman aged 58, is moderately severe and there is retinitis. Both were suffering from marked glycosuria before admission to King's College Hospital, but a diet of 45 grams carbohydrate, 70 grams protein, and 135 grams fat in Case A and 35 grams carbohydrate, 50 grams protein, and 105 grams fat in Case B, rendered them aglycosuric with normal blood sugar after two weeks in hospital. A diabetic condition was then reproduced by the gradual addition of bread to the above fixed diets ultimately 9 oz a day to Case A and 6 oz to Case B. The total glucose excreted in the urine was estimated daily, and when constant 1 oz of fresh raw pancreas was added to the daily diet in the form of a sandwich which they disliked very much. This pancreas was supplied by the courtesy of the British Drug Houses in the same fresh frozen condition which they find yields the maximum of insulin and was eaten within half an hour of removal from the ice chest. All the conditions of the experiment were kept constant, and the figures are recorded in the following table. One ounce of pancreas was given for a week—these days are indicated by an asterisk. Only two days before and after the administration of pancreas are recorded.

Days	Grams of Glucose Excreted		Days	Grams of Glucose Excreted	
	Case A	Case B		Case A	Case B
1	15.2	70.2	6*	16.75	137.14
2	14.9	137.0	7*	23.4	123.88
3*	22.54	142.88	8*	17.5	130.03
4*	13.31	135.39	9	12.49	119.81
5*	17.75	126.2	10	14.82	133.48

1 oz pancreas given by the mouth

The amount of glucose excreted in both cases is very constant considering that over 100 grams is being lost in one case and the difficulty of collecting complete samples of urine in a busy general ward. The first figure in Case B is much lower than the rest because her preliminary stabilization had to be hurried on account of the retinitis, and because she threatened to leave hospital to attend a wedding. An extra 3 oz of bread had been added to her diet only three days previously, and the full effect of this was not manifested until the second figure recorded.

It seems clear from the figures that the administration of raw pancreas had no effect on the amount of glucose excreted, and did not enable these two diabetics either to store or burn more sugar. I find it difficult to avoid the conclusion that the beneficial effect of raw pancreas which has been recorded in your columns was obtained by concurrent dietetic treatment, and not by the virtue of pancreas by the mouth—I am, etc.,

R D LAWRENCE

King's College Hospital London July 3rd

### BRITISH MEDICAL WOMEN FOR INDIA

SIR,—My experience may be of interest to "Medical Woman" who asked in the BRITISH MEDICAL JOURNAL of June 27th (p 1195) for information about work in India. I worked there for several years, chiefly in the mission field. I returned to England a few years ago, for private reasons, unconnected with health. I was always well while I was abroad, and stood a very hot climate much better than most Europeans (for example, I could walk six miles when the thermometer was 115° in the shade). I learnt two Indian languages well, and a little of others. I learnt languages quickly. I passed the examinations for those two in half the usual time, getting over 90 per cent marks. Recently I have taken up another language, quite different from any I have learnt before, and in a month have learnt enough to read the New Testament fairly easily.

As I am now entirely free, have no dependants, and wish to go somewhere where workers are needed, I have lately applied to several societies to be sent abroad again, anywhere. But so far I have not found any to do this. The reason given is that my age is over 35, and they have so many applicants, while funds are so low that they must stick to age limits. I have good testimonials, medical and otherwise. I am told that Government appointments in India are usually given to Indians. In South Africa a three years' preliminary residence is essential.

Private practice could probably be obtained in some parts by anyone who had capital enough to wait for it, and could learn languages and understand the people. I also should be grateful if those who talk so glibly about the East absorbing surplus medical women would explain clearly how and where—I am, etc.,

July 5th

ANOTHER MEDICAL WOMAN

SIR,—For nine months I have tried to get any sort of medical work abroad, in India or any colony, with the most complete success. I have an honours arts degree and the Diploma in Tropical Medicine, the latter the Colonial Office considers of sufficient value to warrant its paying the fees for the course for many of its men applicants.

An application to the Colonial Office brought a lugubrious reply, kindly letting me know the worst at once. While

<sup>1</sup> Brain London 1904 vol xxvii pp 170 178

<sup>2</sup> Aided by a grant from the Medical Research Council.

my application would be "carefully considered," there were very few posts open to women. An application to the Duffield Fund had no result whatever.

There remain the missionary societies and private practice. The former can be possible for relatively few people. In the first place, several societies put applicants through a theological mill which grinds exceedingly small. Secondly, there is a barrade of intimate religious questions which, to anyone with a quite ordinary amount of reserve, are very objectionable to answer, to a committee of strangers especially. Thirdly, while the problem of keeping body and soul is closely united as possible on £150 a year in a tropical country has quite a lot of intrinsic interest, considered as a puzzle of personal application it is unlikely to have much attraction for the ordinary mind.

In India (the native States excluded, where the native product is preferred) private practice presents the most hopeful prospect, but this is by no means so shining as some, usually non-medical, enthusiasts would have one believe. The intending practitioner must have sufficient capital to live on for a year, she will have to compete with not only an ever-increasing number of native women doctors, but with the many doctors, with the bazaar medicine men, who can tell by feeling a pulse whether it is the tibia or fibula which is fractured—but who have the confidence of the people, and with the missionaries who do private work. She will have to learn a new language or languages, to learn the quite intricate ropes of a strange country, to try to understand a strange and by no means simple type of mentality, and she must be able to carry on in the heat month after month. If one has not friends there, putting up one's plate in an Indian town is a somewhat grim vision.

The melancholy truth is that there are too many doctors, and far too many women doctors. This statement of a very obvious fact is naturally not popular with medical school authorities, but the students know all about it when they qualify and think that their troubles are over.

If I am wrong, perhaps these apparently mythical providers of lucrative or any other kind of jobs will take on flesh and blood, come out of the impenetrable darkness in which they are shrouded, and come down to brass tacks. Most important of all, perhaps they will give us their postal address.

The higher caste, too, who turn up periodically and is good enough to inform us, *ex cathedra*, that the reason why medical women cannot get work abroad is that they are unwilling to undertake the responsibility which the pioneers (*requiescant in pace*) undertook—perhaps she will tell us whether she ever had a job in the tropics, if so, how she managed to get it, if not, the adoption of a less lofty tone on her part would be more suitable.—I am, etc.,

A WOMAN G.P.

### BRITISH SOCIAL HYGIENE COUNCIL

SIR,—The real importance of the decision of the National Council for Combating Venereal Diseases to change its name to that of the British Social Hygiene Council lies in the intention to embark on a wider constructive and preventive effort, which will embrace not only venereal disease but all disease and inefficiency, in so far, that is, as voluntary effort in co-operation with Government action can render effective service in such a campaign.

The undertaking of this forward movement indicates some important facts. It illustrates the tardy but growing recognition by voluntary societies and by Government departments of the essential unity which underlies bodily, mental, and moral health. Further, it shows that we are beginning to realize that before we can establish a vigorous and healthy or a happy population in this or in any other country, we must individually and collectively appreciate and understand the intimate association which exists, not only between health and conduct, but also between conduct and health.

In the increasing complexity of our modern civilization, national well-being depends more and more on the conduct of the individual citizen. This fact stands out very clearly in the case of venereal disease in its relation to sexual

promiscuity, hence the urgent necessity for building up a "national health conscience," a real appreciation of the fact that it is "wrong to be ill" if the illness be preventable, just as it is "wrong to be ignorant" now that education is available for every citizen. It is even more important still to arouse in the minds of our people a "racial conscience," a pride of race which will enable an enlightened public opinion to focus attention on the great responsibility which rests on every individual to place the interests and the welfare of the young, and of the next and succeeding generations, in the very forefront of every progressive movement.

These and other considerations surely provide an abundant justification for the decision of the Council to aid to the utmost extent the movement for providing for the adolescent population sound instruction and wise advice in the principles which underlie the right living of the sex life, in short, in sex hygiene in its wider physical, mental, and moral aspects.

The outstanding feature of our present-day social life is the fact that parents are not giving such instruction to their children on any adequate scale. The churches and other religious bodies have so far failed to fill up the gap. Our scheme of national education has not devoted that attention to instruction in personal, sexual, and social hygiene, or to citizenship in the wider sense, which the vital importance to the nation of the subject demands. The causes of this educational failure are complex, but the consequences are apparent in the youthful life in our cities. But if we are to hold our own among the nations of the world this gap must be filled. Instruction and guidance in health and right living in every department of life, individual and communal must be given to the young, and it must be given to boys and girls at the right time and at an age when it can be of real use in building up character. The difficulty is that at present teachers are not available. It will be necessary to start with the training colleges and build up a body of teachers fitted, both by natural inclination and by special training, to instruct and advise the youthful population in sex hygiene, and to help the parents in teaching their children.

The great work which the British Social Hygiene Council under its old name has already done in opening up the field, and in building up a sounder public opinion in the matter of the sex relationships, will be of the greatest help in bringing about further progress.—I am, etc.,

C. J. BARN, CMG, FRCS.

Vice-Chairman, Medical Consultative Council, Ministry of Health.  
Member of the Industrial Fatigue Research Board.  
Vice-President, Leicester Royal Infirmary.

### DISEASES DUE TO FASHION IN CLOTHING

SIR,—I do not think that Dr. Parkes Weber and I differ very profoundly as to either of the two diseases under discussion. The erythema I was referring to was exactly the same as that exhibited by his cases. I am familiar with the reticulated mottling due to sitting before the fire seen so often in delicate persons and old people. What I am not sure about is that there are not other factors than mere dry cold determining the incidence of the erythema described by Dr. Parkes Weber. I question whether dry cold alone produces chilblains, and, as I stated, I believe this condition to be practically chilblain modified, in that the area affected is often very extensive, not the usual situation associated with chilblains, and not so much accompanied by itching. Chilblains are more common in some types of circulation, are most commonly seen on the feet, the hands, and the face, especially on the nose and ears, and I think that dampness as well as cold and frost has something to do with their production. Frequent changing of socks, so avoiding the slight dampness that results from the socks when worn any length of time, is a preventive. The dampness results from want of free evaporation of the moisture from the skin, such evaporation being prevented by the leather of the boot. Boots that are lined, and some kinds of leather, are better in this respect than others, because of being more pervious. The worst kind of leather for boots in cold weather is

patent leather Rubber overshoes have this disadvantage, but it is made up for by the fact that they keep moisture from getting into the foot, and they also keep the cold outside moisture or slush further away from the foot. Hands that are not put much in water are also more free from chilblains. When the nose and ears are affected it is often after being exposed to frosty, foggy weather, or sleet and snow. Exposure to heat before the fire after the chillings above referred to undoubtedly aggravates the condition. I believe the same conditions apply to the extremities of the legs.

The cases I have seen have been in girls wearing artificial silk stockings. Perhaps some chemist or physicist can say whether artificial silk is more likely to absorb and retain moisture as in frosty and foggy weather than natural silk or the fibre of wool. Wool certainly does not cling so closely to the skin, and the stockings are thicker than silk. But whether silk may actually retain moisture in damp, frosty, or foggy weather might be a point of interest. Whilst, therefore, cold is the initial cause, as Dr Weber states, dampness and exposure to a fire aggravate it.

As regards chlorosis, I believe Dr Weber is right in showing the important part taken by the tight corset in its causation, but there are some considerations that make it difficult to believe that it is the only cause.

Chlorosis has been known from the earliest times. I believe it was known to Hippocrates. It was described under its present name by Varicoll in 1620, Sydenham has a chapter on it about 1660-70. It was known to Willis, Boerhaave, and Cullen (seventeenth and eighteenth centuries), and was common in the nineteenth century. I am not familiar with the changes that have taken place in ladies' dress fashions, but is it a fact that ladies have worn tight corsets during all those periods? This is not the first time that corsets have been blamed for it.

I agree with Dr Prakes Weber that rest in bed for a short time and administration of iron was the best line of treatment, but as he has seen cases recover under rest and iron in a basement, so I have often seen cases recover under no other form of treatment than rest, plenty of fresh air, and mild laxatives, iron not being necessary if rest was combined with other hygienic conditions. The reason that rest was necessary—at least at the beginning of treatment—was that the oxygen carrying haemoglobin in the blood was often so far reduced that it was too great a strain on the heart, digestion, and other parts of the system for the girl to indulge in any sort of exertion, especially when she was wearing tight corsets.

While the tight corset has been largely discarded in recent years, there has probably been a greater change in the life and habits of civilized girls during the last twenty years than there had been during the previous twenty centuries. As I stated in my previous letter, the cult of fresh air, along with free movements and exercises in the open air, have been welcome changes in the habits of girls. The tight corset, therefore, important as it was as a causative agent, was, I believe, only one cause amongst several—I am, etc.,

Leith, June 28th

WILLIAM ELDER

### ULTRA-VIOLET LIGHT

SIR,—Mr A. Blakston, in your issue of June 20th (p. 1153), states that the cost of a tungsten arc lamp is £300 per 1,000 hours worked. A tungsten arc lamp of the "Dr. Percy Hall" type has been in use in a municipal clinic of this city for the past fifteen months. Careful records of the cost have been kept, and they work out as under:

	£	s	d
Electricity—1 unit per hour at 5d per unit for 1,000 hours	20	16	8
Tungsten electrodes cost 1s 0½d per hour for 1,000 hours	52	1	8
Total	£72	18	4

—I am, etc.,

W ALLEN DALEY M.D.

Health Department Guildhall,  
Hull June 23rd.

### MEDICAL MEN ON THE PIPE ROLLS

SIR,—I think that both your readers and Mr R. R. James (June 27th, p. 1189) will be interested to learn that the earliest Pipe Roll entry referring to a "Medicus" is to be found in the Roll for Notts and Derby of 1129-1130 (31 Henry I). It is as follows:

Gislebertus de Plesni medicus reddit compotum de 45 marcis argenti pro terra et filia Johannis de Monte Calvino. In thesauro £4 et debet £26.

This means that Gilbert paid the King £30 for a licence to marry the heiress of Monte Calvino. He paid £4 on account in 1129-1130, leaving a balance of £26 to be paid during the next financial year. To judge by the amount of the "fine" Johann must have been a wealthy bride—I am, etc.,

Clifton Bristol July 2nd

R S S STATHAM, M.D.

### Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

THE House of Commons has this week given a second reading to the Unemployment Insurance Bill and has debated the trade outlook and the difficulties of the coal mining industry. Speaking in the House of Lords, Lord Birkenhead, Secretary for India, said that the position of the civil services in India would be one of the subjects to be investigated by a Royal Commission on Indian Government. Until public servants in India could feel that unfair or capricious criticism would neither be voiced nor tolerated by Indian politicians the reservations made by the Montagu Chelmsford scheme to protect civilians, even in transferred services, would remain necessary.

### M. Spahlinger's Treatment for Tuberculosis

A special meeting of the Parliamentary Medical Committee, on Thursday, July 2nd, received a report from five members of its committee who, though not as representatives of the committee, had visited Geneva between June 19th and 25th to investigate the Spahlinger method of treatment for tuberculosis. The report, which was a full one, was discussed at length by the Medical Committee, and several members who had previously investigated the Spahlinger system compared the party's experiences with their own. The committee had prepared recommendations, but in view of the fact that M. Spahlinger was expected in London at an early date for a conference, these recommendations were not pressed, and it was decided not to publish them at present.

The report to the committee was signed by Dr Watts, Dr Selter, Dr Vernon Davies, Dr Drummond Shiels, and Dr J. H. Williams. They stated that one of their number had special experience in the conduct of a bacteriological laboratory, and several had years of clinical experience with large numbers of tuberculosis cases. They stated that all questions put to M. Spahlinger and his fellow workers had been answered without reserve, and that experimental and clinical records were placed at their disposal. Each of the party examined about fifty patients who had suffered or were suffering from tuberculosis and had been or were being treated by M. Spahlinger's methods. The party found M. Spahlinger to be a highly skilled bacteriologist, with great knowledge of electrical and physico-chemical apparatus. They were satisfied that he was not actuated by personal or selfish motives, and had refused to allow his discoveries to be commercialized. The equipment of the Spahlinger laboratories was as good as the party had seen at any university.

### Description of Method

The report presented by the members of the party which went to Geneva was to the following effect:

M. Spahlinger had produced two types of remedial for tuberculosis: (1) antitoxic serum to give passive immunity and to act as a directly curative agent and (2) vaccines or antigens made from cultures of specially exalted strains of tubercle bacilli and fractionated by a method devised by himself. He had devised methods whereby the tubercle bacillus could be stimulated *in vitro* to produce quantities of virulent and differing acetoxins. He stated that the bacillus did not ordinarily produce toxins of this kind in culture media, and only threw these out when its life was threatened. At certain regular intervals he subjected the cultures to physico-chemical conditions which proved irritative or harassing to the organism. For example, a culture was maintained under ordinary laboratory conditions at 37° C. for twenty-one hours out of the twenty-four, and the temperature was then raised to 38° C. for the next three hours. During these three hours toxin was manufactured. At the end of the three hours period the temperature of the incubator reverted to 37° C., and continued at

that figure for another twenty one hours. Analogous methods also used were lowering the temperature, freezing agitation and exposure to light. Spahlinger believed he had isolated at least 21 or 22 different toxins, obtained either as above (ectotoxins) or derived indirectly from the bacillary bodies (endotoxins). One of these toxins produced erysipelatous nodules when injected into susceptible animals, another had a purely pyrogenic effect, and so on. He used each of these separately to immunize horses and to obtain a corresponding specific antitoxic serum. These serums he described as "partial" serums. A "complete" serum was one which contained a mixture of all the partial antitoxic serums in addition to an antibrucella serum obtained by immunizing a horse with the micro-organisms which caused mixed infections and with massive cultures of tubercle bacilli killed by exposure to light. Spahlinger stated that cultures killed by heat or carbolic acid lost certain of their important specific qualities in the process. At present no complete serum existed, though there were still about eleven horses yielding partial serums. Vaccine or antigen preparations also were not obtainable in bulk, chiefly on account of insufficiency of staff, though a certain quantity could be got ready in six or eight months.

The treatment consisted of injecting antibodies subcutaneously two or three times a week, sometimes every day or even several times a day in very acute and advanced cases. The length of the treatment varied according to the gravity of the case. The particular class of serum used depended upon the type of case. For pulmonary tuberculosis there must be a preponderance of antituberculous. For surgical tuberculosis a preponderance of anti-endotoxins was found best and a mixture of serums prepared by the use of human and bovine strains of the bacillus was employed. Chronic and afebrile cases could be treated with vaccines and without antitoxins from the commencement. A complete clinical recovery could be brought about by the means of serum alone, but a relapse or a remission was probable until passive immunity had been converted into active immunity. In eliciting active immunity various antigenic solutions derived from bacillary protoplasm were injected separately into the patient. The total treatment extended over about six months though advanced cases might require a second course of treatment. Spahlinger stated that he had devised a method whereby repeated doses of serum up to 20 ccm could be given to cases without causing anaphylaxis.

Up to the present about 600 cases were known to have been dealt with by M. Spahlinger and at least 250 could be traced and examined. A number were Russian prisoners of war who were detained in Switzerland and had disappeared.

The party reported that they had examined about 50 patients, some cured and well, some partially cured and in process of recovery and some who were just commencing treatment. Amongst the latter were several of the gravest severity, which by no means of treatment at present known to science could be expected to recover. The clinical records of certain cases showed that persons who now appeared perfectly fit and well were originally suffering from an advanced stage of consumption. When the party saw them the only evidence of their original condition detectable was some patchy dullness indicating where the lungs were healed by fibrosis. There were no moist or adventitious sounds of any kind and the temperature was normal. The sputum examined and reported upon by independent medical observers attached to hospitals etc. was negative. Some of these people were following unhealthily occupations in a very bad environment yet remained well. Scarcely any of the patients had been treated by Spahlinger's remedies under suitable hospital or sanatorium conditions. Many of them remained at work though their temperature was well above normal. Cases of healed surgical tuberculosis were also shown though the pulmonary cases were the more striking. A number of cases had been treated from eight to twelve years ago and had remained well without relapses during that time.

The party came to the conclusion that on the evidence presented a *prima facie* case had been made out for the Spahlinger treatment. They recommended that an exhaustive trial should be made under test conditions as soon as it was possible to obtain a sufficient quantity of the serum and of the vaccines. The report then referred to the financial difficulties of M. Spahlinger which were declared to be acute. Progress in manufacturing serum and the report of the party continued to be plainly understood by the public that there was no hope of securing treatment by Spahlinger's method at the present time and that it would be useless for patients to apply for treatment. The only method of facilitating the development of the treatment was by the immediate provision of funds followed in some months time by the distribution of enough of the remedy for a really satisfactory test to be made under the strictest conditions.

After a discussion, during which some members of the Parliamentary Medical Committee expressed the view that the matter lay outside its province, the following resolution was adopted:

That the Parliamentary Medical Committee has received with much interest the account of the visit to the Spahlinger establishment which the five members of the committee have drawn up not as a delegation from the committee but as private individuals. The committee are of opinion that a *prima facie* case has been made out for further investigation but the committee resolve that they cannot as a corporate body, take any action in the matter.

**Indian Medical Service.**—On July 6th Sir Pichay Luce asked the Under Secretary for India if the Government had yet arrived at

conclusions as to the future of the Indian Medical Service and whether it was its intention to carry out the proposals of the Lee Commission in this respect especially in the matter of establishing provincial medical services the members of which would not be under the control of the Secretary of State for War. Under Secretary for India replied that the Government of India's proposals were now under the consideration of the Secretary of State who hoped to arrive at early decisions and would make no further statement could be made.

**The Harnett Case.**—Lord H. Cavendish Bentinck asked the Minister of Health whether he would advise the Government to pay to Mr. William Smart Harnett an adequate sum in compensation for his detention in various mental hospitals in regard to the fact that Mr. Harnett had been found by a jury to have been sane when detained by Dr. Bond and for the rest of his detention and that this opinion had not been upheld by either the Court of Appeal or the House of Lords by which tribunal Mr. Harnett's case had been heard. Mr. Neville Chamberlain replied that he did not think that any claim for compensation out of public funds could be substantiated. No event of the Crown was involved other than Dr. Bond and as a new trial had been ordered against Dr. Bond the matter was still *sub judice*. The Lord Chancellor in his judgement dismissed Mr. Harnett's appeal expressly pointed out that it was not in fact proved at the trial nor found by the jury that the appellant was of sound mind between the date of his alleged detention by Dr. Bond and his subsequent escape from custody.

**Insurrection in Foul.**—On July 7th Sir Kingsley Wood informed Mr. A. Alexander that the Minister of Health hoped that the Public Health (Insects) Bill in Foul etc. for alterations would be submitted to Parliament before the summer adjournment. Considerable modifications had been made in the original draft and a full discussion between the officers of the Ministry and the interests involved. The coming into force of the regulations would be postponed to enable necessary adjustments to be made by the trades concerned and during that period a decision might be arranged in the House of Commons if there was a general election for it.

**Rock Drilling.**—On July 7th Colonel Lane-Fox (Secretary for Mines) informed Mr. D. Grenfell who asked a question as to the prevalence of phthis among men engaged in rock drilling by the use of compressed air machines that he was not in a position to give any general conclusions. The inquiry that had been made was confined to three mines. Its result was to support the apprehension that in the three mines rock drilling might be dangerous to health. He had arranged for a more extensive inquiry at once. The inspectors were taking up the question of precautionary measures at the three mines.

**Ophthalmic Benefit.**—Mr. Bennett asked the Minister of Health whether as a result of the new model scheme for the provision of ophthalmic benefit by approved societies the charge for ophthalmic examination of the applicant had been raised from 5s. the fee paid to qualified opticians to £1 1s., the fee charged by ophthalmic surgeons. Mr. Chamberlain said he was aware that the cost under the new scheme might in certain cases show the increase stated by Mr. Bennett but there would be no charge for the insurance doctor's recommendation, and the new arrangements had been generally accepted by the approved societies.

**Medical Sanitary and Research Expenditure in Tanganyika.**—Mr. Amery, the Colonial Secretary, on July 6th told Mr. Barclay Harvey who asked the amount spent on medical and sanitary services and research work by the Germans in Tanganyika in 1913 and the corresponding figures in 1923-24 that the amount provided in the German estimates for 1913 was approximately £99,000 converting the mark at 20 to the £. This did not include expenditure by certain local bodies to which grants were made for a variety of purposes including expenses connected with hospitals and sanitation which were not shown separately in the estimates. The amount provided for similar services in the estimates for 1923-24 was approximately £116,700, which included all expenditure on buildings.

#### Notes in Brief

Of fourteen local authorities mentioned by the Chief Medical Officer of the Ministry of Health in his report for 1923 as not providing medical inspection for visual defects in school children all save one are providing or have proposed to provide such treatment.

The Ministry of Health is aware of the pollution of the river Lea with sewage and is making efforts to obtain proper treatment and disposal of the sewage. Two of the local authorities are improving their disposal works and a bill is before Parliament for taking the sewage of two others into the London main drainage system.

It is not the intention of the Government to take any further steps with regard to the proposed International Convention for bidding night baking. Its decision not to ratify has been previously announced. Night baking has been prohibited in fifteen European countries.

The Admiralty has reduced the number of landing sick berth attendants by forty-nine as dental attendants in harbour establishments formerly rated as such are being replaced by civilians.

Sir Kingsley Wood announced that before sanctioning the setting up of institutions by local authorities for the use of artificial light the Minister of Health would satisfy himself that a doctor experienced in this work was available.

## Obituary

T MARK HOVELL, F.R.C.S.D.,

Consulting Aural Surgeon, London Hospital. Consulting Surgeon, Hospital for Diseases of the Throat, Golden Square

THE death of Mr Mark Hovell, on June 30th, severs another of the few remaining links with Morell Mackenzie and the beginnings of laryngology in this country. He was the son of Dr D de Beidt Hovell of Clapton, at one time president of the Hunterian Society, and received his medical education at the London Hospital. He took the diploma of M.R.C.S. Eng. in 1875 and the F.R.C.S. Ed. in 1880, and was appointed surgeon to the Hospital for Diseases of the Throat, Golden Square. He assisted Sir Morell Mackenzie in the preparation of his *Diseases of the Throat and Nose*, and in 1887 Mackenzie invited him to take medical charge of the Crown Prince Frederick. Mr Hovell remained in constant attendance on his illustrious patient after he became emperor, until his death in 1888, and was decorated at his accession with the Order of the Crown. On his return to London he was appointed aural surgeon and lecturer on diseases of the throat at the London Hospital. He was president of the Section of Laryngology and Otology at the Annual Meeting of the British Medical Association in 1901, and president of the Section of Laryngology of the Royal Society of Medicine in 1917. Mr Hovell was the author of a well known book on *Diseases of the Ear and Nasopharynx*, which reached a second edition, and he published many articles on otolaryngological subjects in this and other medical journals. Last year he published an interesting and practical work on *Rats and How to Destroy Them*, founded on experience gained at his country house near Hatfield, this volume received high praise from the scientific and other journals at home and abroad, and is recognized as the standard work on the subject.

Although Mr Hovell's characteristically conservative views on the tonsil gave rise to a good deal of discussion more than once, he was admired by his colleagues as a surgeon of very wide experience and sound judgement, notable for his thoroughness and common sense.

He married in 1905 the Hon Margaret Cecilia Bateman-Hanbury, daughter of the second Lord Bateman, and leaves one son.

CHARLES F HARFORD, M.A., M.D. CANTAB.

WE regret to announce the death of Dr C F Harford on July 4th at his home in Harpenden. He was well known for his practical interest in a variety of subjects—medical missionary work, temperance reform, tropical medicine, ophthalmology, and (during recent years) psychotherapy.

Charles Forbes Harford was born at Keswick in 1864, the youngest son of the Rev Canon Harford-Battersby. From Repton he went to Trinity College, Cambridge, and studied medicine at St Thomas's Hospital. In 1889 he obtained the diplomas of M.R.C.S. and L.R.C.P. Lond., and graduated M.B., B.Ch., proceeding M.D. in 1892. After acting as ophthalmic assistant at St Thomas's and Moorfields, he went out, in 1890, as a medical missionary to Lokoja, West Africa. Three years later he returned to England, and was appointed principal of Livingstone College, Leyton, which he had helped to found in order to supply elementary medical instruction for candidates for the mission field. He held that post until the outbreak of war, when he obtained a temporary commission in the R.A.M.C. From 1914 to 1919 he served in France and England as ophthalmic specialist with the rank of captain, and after demobilization he carried out corresponding duties under the Ministry of Pensions. Since the war he had acted as oculist to school children under the London County Council and the Herts County Council, and as refraction assistant at St Bartholomew's Hospital.

For fifteen years Dr Harford was secretary to the medical committee of the Church Missionary Society, and advisory physician to the society, he had been joint secretary of the Royal Society of Tropical Medicine and

Hygiene, and instructor in health to the Royal Geographical Society, of which he was a Fellow.

Throughout his career he worked for the cause of national sobriety, and in 1919 he was secretary to the Church of England Temperance Society. He was a fluent writer, and many articles and letters from his pen appeared on this subject, as well as on psychotherapy and on psychology in its relation to problems of vision. His book, *Mind as a Force*, appeared last year, and was reviewed in our issue of November 29th, 1924. He served for a time as editor of *Climatic*.

Dr Harford married Adeline, daughter of Mr William Clapton, F.R.C.S., and had one daughter. The funeral took place at East Hyde on July 7th. A memorial service will be held at Livingstone College, Leyton, on Tuesday, July 14th, at 4.30 p.m. The Bishop of Barking will officiate. Friends are invited to attend.

We are indebted to Mr W McADAM ECCLES for the following appreciation. My friendship with the late Dr Charles F Harford, known then as Charles Harford-Battersby, dates back to 1887, when, as a student at St Thomas's Hospital, he was a fine cross-country runner, out-distancing most of us from St Bartholomew's. He qualified in 1889, and in 1890, to the surprise of some, he went out as medical missionary for the Church Missionary Society to Lokoja, West Africa. It was his sojourn in this mission field which gave him his insight into the need of elementary but sound knowledge of health matters for those proceeding to spheres where lurked serious dangers to health, and he spent a large part of the rest of his life in seeking to remedy such a lack of knowledge. In 1893, in association with the late Dr Harry Guinness and myself, he founded Livingstone College and became its first principal. Here hundreds of men and women have received an elementary training in medicine, surgery, hygiene, nursing, and cooking which has stood them in good stead when alone in the outposts of empire, miles upon miles away from qualified medical aid. Later his work as secretary of the medical committee of the Church Missionary Society, and physician to the society, so thoroughly carried out, led to far-reaching improvements in many branches of the society's work abroad. Keenly interested also in social reform, particularly in the question of the abuse of alcohol, he acted for a while as secretary of the Church of England Temperance Society, and of the Native Race and Liquor Traffic United Committee, and was diocesan reader in London, St Albans, and Chelmsford dioceses. Fearless, apt at times to be dictatorial, but always because he felt that the right must be championed, and imbued with great energy, everyone who came in contact with him could not but feel that they had met a true and earnest man, keen to help where his knowledge was useful, ready to draw swords with those from whom he differed, but always as a Christian gentleman. With his work in ophthalmology and tropical medicine others more competent will doubtless deal. Working, writing, speaking, and active to the very day before his death, all his friends will say, "Well done, enter into rest."

R H SCANES SPICER, M.D. LOND.,

Consulting Surgeon for Diseases of the Throat, St Mary's Hospital

WE regret to record the death, in his 69th year, of Dr Robert Henry Scanes Spicer, which took place on June 18th. He was the son of Dr Scanes Spicer of North Molton, Devon, and received his medical education at St Mary's Hospital, where he gained an entrance scholarship in natural science in 1877, and was demonstrator in anatomy in 1879. In 1877 he graduated B.Sc. in the University of London, and he took the diplomas of M.R.C.S. Eng. and L.S.A. in 1882. He took the degree of M.B. Lond., with honours, in 1882, and proceeded M.D. in 1885.

Dr Scanes Spicer held the post of medical superintendent of Fulham Poor Law Infirmary from 1884 to 1888. He studied in the leading throat clinics in Vienna, Berlin, and Paris, and was appointed surgeon for diseases of the

throat at St Mary's Hospital in 1888, an appointment which he held until 1908, when he was made consulting surgeon. He took a leading part in founding the Laryngological Society of London, and was jointly the first secretary, and subsequently vice-president, he was also one of the founders of the Otological Society of Great Britain. In the British Medical Association he was honorary secretary of the Section of Laryngology in 1890, vice-president in 1895, and president in 1900. He was also a Fellow of the Royal Society of Medicine.

He contributed an important original paper on cancer of the throat to this JOURNAL in 1909 and several other papers on the same subject were published in the *Proceedings of the Royal Society of Medicine*. He held interesting and original views on posture and respiration as causative factors, which, however, were not endorsed by his colleagues. Dr Scanes Spicer was an excellent laryngeal and nasal operator, in fact, the widely employed Caldwell-Luc operation for empyema of the antrum of Highmore might equally correctly have been called the Scanes Spicer operation, as he introduced it in London simultaneously with Caldwell in New York and Luc in Paris. He retired from practice in 1913 owing to impaired health, but returned to work under the Ministry of Pensions until a more serious breakdown in 1922. He leaves a son (who was head boy at Eton in 1917, and afterwards took a first class in the Classical Tripos at Cambridge) and two married daughters.

#### ERIC SINCLAIR, M.D.,

Inspector General of Mental Hospitals, New South Wales.

Dr. ERIC SINCLAIR, Inspector-General of Mental Hospitals in New South Wales, who died recently while on a tour of inspection, was born in Greenock in 1860, and received his medical education at Glasgow University, where he graduated M.B., Ch.M. in 1881 and M.D. in 1886. After serving as house surgeon and house-physician to the Western Infirmary, Glasgow, he entered the New South Wales State Public Service in 1882, and two years later assumed control as medical superintendent of the Gladstone institution. In 1898 he succeeded the late Dr. F. N. Manning as Inspector-General of Mental Hospitals, which post he continued to hold up to the time of his death. He took great interest in improvements in the treatment of insanity, and instituted a system of training of nurses and attendants. The establishment of a chair of psychiatry in Sydney University was largely due to Dr. Sinclair's continual advocacy. He further instituted in New South Wales the system of admission of voluntary patients to mental hospitals. He is survived by two sons, both of whom are members of the medical profession.

Dr. H. C. McDONNELL writes:

Eric Sinclair, who passed away so dramatically in the train on May 19th—literally in harness, as he was on his way to inspect the new mental hospital at Orange—was a man of very exceptional character and attainments. He had for some twenty-seven years shouldered alone the whole of the organizing and development work, as well as the administration, of the Lunacy Department of New South Wales, and, in addition to this, during the later period of the great war took on the onerous and anxious work of principal medical officer of No. 2 Military District (New South Wales), with the rank of lieutenant-colonel.

He was a man with great capacity for detail, and he loved to plan out for himself the minutest specifications of the new buildings he was projecting. He was essentially an up-to-date man, and a desire for the amelioration of the lot of those suffering from mental illness with a clear view of possibilities of improvement in their treatment, especially in the direction of removal of restrictions, was an outstanding feature of his administration of an office which is at present constituted, necessitates great self-reliance and responsibility in the holder. Dr. Sinclair reached the compulsory retiring age early in the present year, and had contemplated giving up his office at the end of last year, as he suffered from some cardiac disability, but at the request of the Government he consented to

carry on for another twelve months, and it was while endeavouring to do so that death cut him off before he had even tasted any of the leisure his long and arduous service to his adopted country had earned for him, for he was a man who had never relinquished the reins of office to take a holiday since his appointment to his high position. It can be truthfully said that Eric Sinclair carried on, developed, and extended the great traditions of the Lunacy Department of New South Wales left by his predecessor in the office of Inspector General, the late Frederick Norton Manning.

#### THE LATE DR. W. J. J. STEWART

Dr. WILLIAM BUTLER writes: A kindly person, a humane doctor, unselfish, upright, and straightforward, Stewart was beloved of his friends, endeared to his patients, trusted and respected as an official. A loyal colleague, his sincerity impressed those who had the privilege of working with him, while his modesty, his unobtrusive strength of character and distastefulness of the loud and thrusting manners so much the vogue of seelers after place, singled him as one who came to his own in virtue of his innate fitness for the office. He so fully and satisfactorily filled the medical superintendent of the Wilkesdon Hospital he had scope for abilities naturally fitting for the position which a long experience in hospital administration and a wide knowledge in the diagnosis and treatment of infectious diseases enabled him to fill with exceptional success. In private life he was esteemed and loved no less than he was respected and admired as a public servant. He was a keen and good sportsman with wide and cultured sympathies, fond of outdoor pursuits, deeply interested in what is known as nature, and his varied appeals to those who were happy to be numbered among his friends will be missed by a privileged circle who will ever treasure his friendship. To his widow, left with a loving memory, the deepest sympathies are widely extended.

#### Medico-Legal.

##### ACTION FOR NEGLIGENCE AGAINST MEDICAL OFFICERS

THE jury disagreed in the action brought in the King's Bench Division by Mrs. Mary C. Venn of Thornton Heath, on behalf of herself and her children, against Dr. R. Veitch Clark, former medical officer of health for Croydon, and general medical superintendent of the Croydon Borough Hospital, Dr. J. M. Todesco, resident medical officer of the hospital, and Dr. G. W. Elder, formerly assistant resident medical officer of the hospital, for damages for alleged negligence in the treatment of her late husband, Mr. William E. Venn, a notary public practising in the City of London. The jury, however, unanimously exonerated Dr. Veitch Clark of any negligence.

The claim which was brought under the Poor Persons Rules came before the Lord Chief Justice on June 23rd and the hearing lasted five days. Sir Henry Maddocks, K.C., and Mr. B. M. Goodman appeared for the plaintiff, and Mr. A. Neilson, K.C., and Mr. T. Carthew appeared for the defendants.

The plaintiff alleged that when her husband was recovering from scarlet fever in 1922 he complained of pain in his leg, and his doctor diagnosed a deep-seated abscess. Mr. Venn was removed to the Croydon Borough Hospital on March 18th, where the plaintiff alleged his complaint was improperly diagnosed as scarlatinal rheumatism until April 25th when Dr. Clark ordered an operation. It was alleged that the operation was too late, and the patient died on June 15th.

The defendants denied negligence.

Sir Henry Maddocks, in opening the case, said that Dr. Milson of Thornton Heath diagnosed the complaint as a deep-seated abscess. The day after the patient was admitted to the isolation hospital Mrs. Venn told Dr. Elder this but Dr. Elder replied that in his opinion, Mr. Venn was only suffering from scarlatinal rheumatism. Mrs. Venn also told Dr. Todesco who said he thought it was a case of mind over matter, and that if Mr. Venn ceased to worry he would soon get better. On April 24th Mrs. Venn saw Dr. Clark, who examined her husband and ordered an operation, which was performed at the Croydon General Hospital on April 26th, a deep-seated abscess being found at the place where Dr. Milson had diagnosed it to exist a month previously.

Dr. E. G. D. Milson, in his evidence said there were medical means by which the presence and locality of a deep-seated abscess could be more or less definitely ascertained, and neglect of such an abscess might result in blood poisoning and death. It would take two or three weeks to produce an abscess of the size of that found when Mr. Venn was operated upon. Cross-examined, Dr. Milson said the hospital authorities appeared to have diagnosed

diphtheria in Mr Venn when he was admitted, and a septic throat might have accounted for his high temperature, but that would not relieve the medical attendant from considering the thigh rheumatic pain was very frequent after scarlet fever.

Mr Neilson K.C. in his opening, said Dr Milson had not suggested that an operation was necessary on March 18th. He sent Mr Venn into hospital for observation, and the reports showed that Mr Venn was carefully observed and that he made no complaint about his leg until April 16th. The trouble was then diagnosed as of a rheumatic nature and nobody could have said that the diagnosis was wrong. Later reports disclosed no complaint about pain in the leg, and on April 22nd inflammation first appeared.

Dr Veitch Clark, in his evidence, said he was not in charge of the patients at the hospital but visited them at the request of the resident medical officers. He was now medical officer at Manchester. When he saw Mr Venn on April 25th he found his leg swollen, red, and tender, and coming to the conclusion that there was an abscess he instructed the medical officers to call in a surgeon. He was of opinion that pus had not been present more than two days and that it could not have been discovered earlier than, possibly the evening of April 23th.

Dr Elder, now medical officer of the Manchester Corporation Sanatorium, said the day following Mr Venn's admission to the scarlet fever ward he examined him, and diagnosed diphtheria. He found Mr Venn suffering from a swelling on the right thigh and Mr Venn told him he was a martyr to rheumatism and that the rash over the swelling was caused by a hot water bottle. He was never told that Mr Venn was suffering from a disease of the leg.

Cross-examined he never diagnosed deep-seated inflammation, but the patient had such treatment as would relieve either a burn or deep-seated inflammation.

Dr Todesco, in his evidence, said on Mr Venn's admission he diagnosed scarlet fever and diphtheria. There was some redness on his right thigh but he (the witness) did not make a diagnosis of it. It was consistent with having been caused by a burn. Mrs Venn told him her husband had been treated for rheumatism, rheumatism was a common complication of scarlet fever. Mr Venn's condition on admission was not consistent with his having a deep-seated abscess.

Cross-examined he did not remember telling Mrs Venn that it was a case of mind over matter, and that if Mr Venn ceased to worry about his leg he would get better.

Dr F. L. Adams, of Croxson, said he saw Mr Venn on April 25th and found him suffering from a large fluctuating abscess. In his view, the formation of the abscess had only begun four or five days before.

Nurse Corney, who was in charge of the double infection ward at the Croxson Borough Hospital in March and April 1922, said on April 18th Mr Venn complained of pain in the leg but there was nothing to be seen. She first saw inflammation on April 20th and by April 22nd the leg had become very inflamed. On admission, Mr Venn told her he had had rheumatism, and that he had been burned with a hot water bottle.

Dr William Hunter, C.B., senior physician to the London Fever Hospital from 1880 to 1925, said he had carefully considered the Harris reports, and other documents relating to the case and he was of opinion that on Mr Venn's admission nothing surgical could have been done. He should have marked the case 'Queer, rheumatism or query something else.'

The jury disagreed.

The Lord Chief Justice asked Mr Neilson K.C., if he was willing to take a majority verdict, but Mr Neilson replied that he was for the defendants.

The Lord Chief Justice: Then you are not willing.

### ALLEGED NEGLIGENCE AT CONFINEMENT

In the King's Bench Division, before Mr Justice Sinker, on July 1st, the jury gave a verdict for the defendants Dr J. L. W. Kitching, Dr R. C. P. Whitcombe, and Dr J. Hale, who practise in partnership at Cobham, in an action brought by Mr A. E. Sherlock, an under gardener employed at Cobham on behalf of himself and his three children, for alleged negligence in the treatment of his late wife in childbirth.

Mr B. B. Stenham appeared for the plaintiff and Mr W. A. Jowitt K.C. and Mr T. Cartwright appeared for the defendants.

Mr Stenham in his opening said the deceased woman was strong and healthy and normal in every way. She had a baby 2 years old, and in 1923 she became aware that she was going to have another. The district nurse was communicated with and Dr Kitching was to be the doctor to attend her at the confinement which was expected on March 7th 1924 but actually occurred on March 12th. The plaintiff's employer Mrs de Jonge, a Dutch lady with some years of nursing experience, observed that the deceased had a certain amount of swelling above the ankles for some eight weeks prior to the confinement and she took tests of the deceased's water and found albumin. She told Dr Kitching who replied that he had found no albumin worth mentioning in his tests, and also that, in his opinion, the patient's physical condition was quite satisfactory but her mental condition was something different. Dr Kitching also declared that Mrs de Jonge had been carrying out tests in front of the patient and marking her beliefs she was ill. Later the patient became lethargic, and Dr Kitching caused her removal to Epsom Infirmary where she died on March 24th. Counsel said the deceased died of eclampsia but if her symptoms had been carefully watched at an earlier stage, and if Dr Kitching had not got a preconceived

notion of what was the matter, she would have had a proper diet and in - - - did not have died.

The - - - said he did not allege anything against Dr Whitcombe, but he alleged negligence against the other two partners. Mrs de Jonge did not prescribe diet for his wife but she out-nursed her with his consent.

Mrs de Jonge, cross-examined, admitted that as the result of another case in which she had interested herself she did not think much of Dr Kitching after that. She had put the plaintiff funds for that action, but she denied encouraging him in it. There was a time when he intended dropping it and she left him perfectly free to drop it. When Dr Kitching reprimanded her for interfering in the case she admitted that she cried and ran away.

Dr Robert Maxwell Trotter of London said, in his opinion Dr Kitching ought to have diagnosed eclampsia on March 17th, 1924. Cross-examined, he said, if Dr Kitching found no albumin before the confinement, in his opinion up to the 16th Dr Kitching had done nothing wrong. If no albumin was found on the Tuesday, he did not think it could be said the patient was suffering from eclampsia.

Dr W. G. Donald of Walthamstow said from the evidence he had no doubt whatever that the deceased died from puerperal eclampsia. Mrs de Jonge's tests of albumin appeared to him to have been normal and proper tests. He did not agree that the symptoms were such as were likely to be those of encephalitis.

Dr Guy M. Kendall, assistant medical officer at Epsom Infirmary, said he made a post mortem examination and found death to be due to eclampsia and cerebral.

Mr Jowitt K.C. in his - - - did not guarantee results and he submitted - - - for the jury to say a case of negligence had been made out against defendants.

Mrs de Jonge was interested in medicine and had that little knowledge which was such a dangerous thing. She was, no doubt, one of the most generous unselfish devoted persons one could wish to meet but he hoped the result of this case would be to hold up a finger of warning to persons against interfering in any way with a case in which a doctor was concerned. It was no part of his case to show that the cause of death was encephalitis lethargica but he would call eminent men who would say that in the light of what they now knew it was more likely to be encephalitis lethargica than eclampsia.

Dr Kitching cross-examined said Mrs de Jonge's tests were not of the slightest value. He thought she was a nuisance. She had no standing in the sick room at all. The deceased's symptoms pointed to a cerebral and mental condition. He, however, had not made up his mind to anything. He thought the deceased's condition entirely due to the atmosphere created about the house and that she was being harried into a mental state. One of the things he objected to was that Mrs de Jonge while discussing the patient's condition practically waved her test tube in the patient's face.

Dr Whitcombe in his evidence said the patient seemed upset and worried. There were several persons in the sick room and the noise was so great that one could scarcely hear oneself speak. There was no symptom of eclampsia.

Dr Hale in his evidence said he and Dr Kitching together examined a specimen of the deceased's urine and found no albumin. When the deceased was removed to the infirmary he wrote to the medical officer asking if he thought it was a case of encephalitis lethargica. He at no time agreed with Dr Kendall that death was due to eclampsia.

Mrs Wakefield, certified midwife who attended the deceased during and after the confinement, said she had had experience of eclampsia, but there were no symptoms in this case which led her to suspect the patient had eclampsia.

Dr J. P. Hedley, obstetric physician to St. Thomas's Hospital, London, said the case in no way resembled eclampsia.

The jury found for the defendants and judgement was entered accordingly.

## Universities and Colleges

### ROYAL COLLEGE OF SURGEONS OF ENGLAND

#### ELECTION TO THE COUNCIL

At a meeting of the Fellows on July 2nd for the election of three Fellows into the Council in the vacancies occasioned by the retirement in rotation of Mr V. Warren Low, Mr James Sherren, and Sir John Lynn Thomas, Mr Sherren and Sir John Lynn Thomas were re-elected and Mr Arthur Henry Burgess of Manchester was elected. 964 Fellows voted including 172 Fellows resident out of Great Britain and Ireland, 961 sent ballot papers through the post and 3 voted in person. The result of the poll was as follows:

Candidates	Votes	Plumbers
ARTHUR HENRY BURGESS	462	48
JAMES SHERREN	441	14
SIR JOHN LYNN THOMAS	406	7
Victor Bonney	361	19
Vincent Warren Low	332	12
John Percy Lockhart-Mummery	243	11
Herbert John Paterson	232	18

Three voting papers were found to be invalid, and in addition three voting papers were received too late.

**DEATHS IN THE SERVICES**  
Lieut Colonel George Tucker Thomas Madras Medical Service (ret.) died in London on June 3rd. He was born on September 25th 1851 the son of the late Rev John Thomas of the Church Missionary Society, Tinnelly and after taking the M.R.C.S. and L.R.C.P. Lond in 1873 entered the I.M.S as surgeon on March 31st 1875. He reached the rank of lieutenant colonel after twenty years service and retired in 1905. Almost the whole of his service was spent in civil employment at first in Madras where when resident medical officer of the Madras General Hospital he came into collision with the Provincial Government in a case which created a good deal of stir and interest in India, some forty years ago, and afterwards in Burma.

## Medical News.

THE publication by the Stationery Office of the volume of general tables comprising population, housing, institutions, ages and marital conditions, education, birthplace and nationality, and the Welsh language, completes the series of volumes of tabulated statistics derived from the census of June, 1921. This final volume contains the aggregated figures of the sixty county volumes that have already appeared, and so renders possible the study of the census from a national standpoint. A certain amount of new matter has been added relating to populations of county court circuits and districts, seamen and fishermen not enumerated with the general population on census night are included, also persons in vessels or establishments under naval, military, or air force discipline outside Great Britain. The price of the volume is 13s., and it may be obtained from H. V. Stationery Office.

A FORTNIGHT ago a leading article was published giving an account of the difficulties which had arisen with regard to reciprocity of medical practice with Italy, and stating that an agreement had been signed under which full freedom of practice in Italy was accorded to British practitioners, the country undertaking to admit medical practitioners possessing degrees from Italian universities to the Foreign List of the Medical Register of the United Kingdom. We learn from Mr. Norman C. King, registrar of the General Medical Council, that the Council has been officially informed that the Italian Embassy in London has communicated to all the consular offices under its orders the regulations concerning the admission of British registered practitioners to the privilege of practising medicine in Italy and its dependencies. The new arrangement comes into force from the date of its signature (May 21st, 1925) without need for further ratification or approval.

THE Fellowship of Medicine announces that a course in the diagnosis and treatment of common diseases of the nervous system has been arranged by the West End Hospital from July 27th to August 14th. A vacation course will be held at the Prince of Wales's General Hospital from August 4th to 15th, including lectures and demonstrations in medicine, surgery, and special subjects, including mental diseases and fevers. At the All Saints Hospital there will be a special course in urological diseases throughout the month. From August 24th to September 5th the Queen Mary's Hospital, Stratford, will give an intensive course in medicine, surgery, and the specialties. The following special courses are announced for September: diseases of the chest, infants' diseases, dermatology, electrotherapy, ophthalmology, and an intensive course at the Westminster Hospital. Copies of the syllabus of each course and the programme of the Fellowship of Medicine may be obtained from the Secretary at 1, Wimpole Street, W.1.

AN announcement appears in our advertisement columns inviting applications for the appointment of two assistant medical officers for the Mental Hospitals Department under the New Zealand Government. The commanding salary is £615 per annum. Particulars may be obtained by sending a foolscap envelope to the High Commissioner for New Zealand, 415, Strand, W.C.2.

THE National Baby Week Council has held during the present week an Imperial Baby Week at Wembley Exhibition. On July 6th Dr. Mary Scharrlieb presented prizes and certificates won in various annual competitions, including the Astor challenge shield for the best local baby week campaign in 1924, awarded to infant welfare centres.

The week film displays and lectures

At the Climatological Congress to be held at Davos from August 17th to 22nd the topic for discussion will be the significance of climate in its physical, physiological, and therapeutic aspects. Those desirous of contributing papers on any branch of the subject, or requiring details of the arrangements, should communicate with the Secretary of the Congress, Dr. Vogel, Eysen, Davos Dorf.

THE German Society for the Promotion of Morality, which represents the German Branch of the International Abolitionist Federation, is bringing before the Reichstag a bill for placing under supervision all persons who are insane, mentally deficient, or who, in consequence of mental, physical, and moral defect, are incapable of looking after themselves and are a danger to others. The supervision will be arranged at the public expense by order of the county court in a suitable family, institution, or workmen's colony.

THE annual dinner of past and present students of St. Mary's Hospital Medical School will be held at the Connaught Rooms, Great Queen Street, W.C., on Monday, October 5th, at 7.30 p.m.

THE St. Bartholomew's old students' dinner will be held on Thursday, October 1st, in the Great Hall of the Hospital, at 7.30 p.m. The chairman will be Mr. John Adams F.R.C.S. The honorary secretaries are Sir C. Gordon Watson and Mr. R. M. Vick.

SUBSCRIPTIONS received at the Mansion House for the Metropolitan Hospital Sunday Fund reached, on July 6th, a total of about £51,000.

A VACATION course of instruction for qualified practitioners will be given again this year at St. Bartholomew's Hospital, beginning on Monday, September 7th, and ending on Friday, September 18th. Inquiries should be addressed to the Dean of the Medical College, St. Bartholomew's Hospital, E.C.1.

DR. GEORGE P. ALDRIDGE of Luton Bolton, has been appointed to the Commission of the Peace for the County Palatine of Lancaster.

DR. MOURIQUAND has been nominated professor of children's diseases in the Lyons Faculty of Medicine in succession to the late Professor Weill. Professor Gott of Munich has succeeded Professor Salge in the chair of children's diseases at Bonn.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, **British Medical Association House, Tavistock Square, W.C.1** on receipt of proofs.

All communications with reference to ADVERTISEMENTS as well as orders for copies of the **JOURNAL** should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are: **VESEUM 9361 9362 9363**, and **9364** (internal exchange four lines).

THE TELEGRAPHIC ADDRESSES are:

EDITOR of the **BRITISH MEDICAL JOURNAL**, *Antology Westcott London*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements etc.), *Antology Westcott London*

MEDICAL SECRETARY *Medicina Westcott London*

The address of the Irish Office of the British Medical Association is 16 South Frederick Street, Dublin (telegrams *Bacillus Dublin* telephone 4737 Dublin) and of the Scottish Office 6 Drumsheugh Gardens, Edinburgh (telegrams *Associata, Edinburgh*, telephone 4361 Central).

## QUERIES AND ANSWERS

### UNCERTIFIED LUNATICS

"P. & D." writes to ask for enlightenment as to a doctor's position with regard to uncertified lunatics. Sometimes (he says) individuals evidently insane walk into one's surgery and sometimes one visits families where insane relatives are kept at home, the relatives refusing to allow certification although the individuals in question are clearly dangerous while at large. What should the doctor do in such cases?

### 'EUPARAL'

DR. A. H. SKINNER (Beckenham) writes: On page 888 of the **JOURNAL** of May 9th in a review of Jordan's *Textbook of Histology* mention is made of a new mounting medium 'euparal'. I find difficulty in obtaining this.

The method of preparation of this mounting medium is described by Shepherd in the *Transactions of the American Microscopical Society* vol. 37 (1918) p. 131. We understand that 'euparal' can be obtained in this country from Messrs. Parry and Tallock, 14, Cross Street, Hatton Garden, E.C.1.

### STREPTOCOCCAL INFECTION OF TONGUE

"G. P." writes to suggest to 'Peppercod' (June 27th p. 1201) that a Wassermann test should be made. In a similar case he has found it positive greatly to the surprise of both the doctor and patient.

### INCOME TAX

L. B. C. has received an inquiry from the local inspector of taxes with regard to the deductions made for domestic servants' wages; he has deducted the estimated cost of food, etc., of one maid at each of the two houses used for the practice.

Our correspondent does not say what staff is employed at each house and a good deal must depend on that—for example, if to take an extreme instance, the staff kept is one resident

maid and one day girl, with occasional assistance it would seem to be unreasonable to charge the whole cost of the maid as incurred in connection with the consulting room, answering the inquiries of callers, and other strictly professional work. A useful working rule is that where two maids, with occasional assistance, are kept, the cost of one maid is probably a reasonable charge but beyond this it is not possible to give general indications. Where it can conveniently be arranged, a personal discussion with the inspector is often the best means of settling this type of question.

#### Expenses Incurred by Locumtenent

"STELLA" did some locumtenent work last year and incurred £6 in travelling to the hospital where the work was done. The inspector refuses to allow this expense as a deduction from the inclusive fee received.

\* \* The difficulty seems to be that "Stella" is not in general practice, and therefore cannot assert that the fees in question were earned and the expenses in connection therewith were incurred as part of his ordinary medical work. The locumtenent work was apparently an isolated matter, and, if treated as such, the expense of going to and from was not earned in the performance of the duty but in order to put our correspondent into a position to perform it. At the same time the expense of travelling from place to place is so natural to the performance of locumtenent work that we should have thought that the inspector would have allowed it, rather than take up what is a very strict and somewhat harsh attitude on the strength of the peculiar features of an unusual case.

### LETTERS, NOTES, ETC.

#### SUMMER TIME

THE secretary of the Early Closing Association writes to say that during the past four years resolutions in favour of the permanent adoption of a six months summer time period have been passed by 1,000 municipalities, trade organizations, chambers of trade or commerce, athletic and other associations. Resolutions have also been unanimously carried at two public meetings at the Mansion House held under the presidency of the Lord Mayor of London, and at large meetings in Birmingham, Bradford, Bristol and Manchester. Deputations have also presented evidence as to the urgency of this matter to the Home Secretary and the second reading of the Summer Time Bill was passed in the House of Commons on March 13th last by 289 votes against 63. Notwithstanding the strong public opinion in favour of this measure and the sympathetic support of the late and present Governments the bill is still in abeyance. Unless public opinion is aroused the summer time period this year will end abruptly in the middle of the holidays—namely, in the middle of September—and at a time when the additional hours daylight from work and business is so much needed.

\* \* The British Medical Association as most of our readers know is strongly in favour of the proposal to make summer time a permanent measure. The Representative Body in 1923 passed a resolution expressing regret that summer time had been curtailed that year as it is of the opinion that summer time is beneficial to the health of the nation and the Council in February 1924 voted 5 guineas to the Early Closing Association towards the costs of its campaign for the extension of summer time and its permanent adoption.

#### URINARY INFECTIONS

DR HAROLD H. SANGUINETTI (London W) writes. In criticizing my paper on urinary infections Dr Irwin (July 4th p. 37) seems to assume a greater ignorance on my part of such infections than I feel is warranted by anything I wrote. The fact that the paper represents a much abridged version of a thesis presented and accepted for the D.M.O. I do not doubt accounts for some misunderstanding but even then it is obvious I did not advocate vesical lavage for definitely descending infections where the seat of the infection remained in the kidney or renal pelvis. What, however, I have suggested is that descending infections are not so frequent as is now usually maintained or alternatively, that in descending infections the focus in the kidney and renal pelvis in many cases clears up some considerable time before the bladder becomes free from infection. The persistent infection of the bladder can be satisfactorily treated with injections of collargol. I am naturally aware that the majority of acute cases clear up rapidly without the use of vesical lavage although in no inconsiderable proportion of these cases the clearing up is confined to the clinical symptoms and organisms persisting in the urine and leading to subsequent relapse. It will be noted that the majority of my cases were chronic cases among whom were at least a few who had undergone in the acute stage just the treatment Dr Irwin advocates. The fact is these cases are patient and medical attendant much trouble and with the treatment usually adopted are difficult to cure. When at a meeting of the Hunterian Society in the discussion of Sir John Thomson Walker's Hunterian Lecture on urinary infections I claimed that with collargol one could get 50 per cent of cures the lecturer—while I think doubtful of my

claim—agreed that a treatment as such it was claimed would give such results as worth careful consideration. My percentage of cures for a certainly small number of cases is considerably higher. We may I think leave it at that. When I have convinced myself that a suitable dilution of silver nitrate is certain, and not only 'probably' just as effective as collargol I shall use it in place of the latter. Meanwhile, I shall, for routine purposes, continue to use collargol.

#### THE JACOMETER

AN ancient Scottish university is said to have invented a Calorimeter for testing its doctors of divinity but in spiritual affairs we have just a man sober who could clearly affirm that "British constitutional prescriptions arbitrarily proposed puzzle the scientific American consulting his barometer, could forecast the next day a flow of liquor over the bar, and from the thermometer give the exact number of its labours." Now as we learn from the British Empire number of one of those publications devoted to the gratuitous postgraduate education of British doctors the American has invented a "jacometer" which shows the "dispositive index" of a suspect and when a "jacometer" attachment has been affixed records accurately the appropriate period of debilitation. The instrument looks like a gas apparatus and a British entomologist thus hums its superiority to our rule of thumb methods.

In epochs of dublety  
Green heral confusion  
We'd test a man's sobriety  
By British Constitution  
We'd stand him perpendicular  
Ask him for truly rural  
Give arbitrarily standard  
In verbiage in the plural  
Dry Yankee scientific men  
Have found a way much subtler  
To tell if chauffeurs or other men  
Have visited the toilet  
Has he had coffee, milk or tea  
Is tested by the jacometer  
For their thanks the meter  
Will clap on the jacometer

Then as his breath comes sighing out  
It disposes a dial  
And should it come to trying out  
The needle stand his trial  
They have a radiant plate beside  
Tells starker from a lamp  
And if one try the blue to hide  
Shows every lit or limp  
The psycho-analyst left behind  
And vitamin an hormone to find  
There's nothing new for man to find  
Outside the land of Mormon  
What need we think the final pains  
What need for someone thicker  
All other folks as give up first  
When the Yankee gives up drinking  
R C B

#### HOLIDAYS

DR W. B. DUNN (Medical Superintendent, Baldovan Institution Dundee) writes. I should be glad to know whether there is any reciprocity between public hospitals institutions etc. with regard to the holidays of members of staff passing from one to another. For example if a nurse who has had six months continuous work in one hospital passes directly to a post in another hospital without a holiday is the latter supposed to grant her the usual full holiday at the end of three months service?

#### COPPER CITRATE IN THE TREATMENT OF LEPROSY

LIEUT. COLONEL F. T. PALMER (Assam) writes to point out an error in our abstract on May 9th (p. 88) of a paper read by him. In one sentence copper sulphate was erroneously substituted for copper citrate. Colonel Palmer adds that copper citrate is used for intravenous injection in doses of 15 grains for an adult and is rendered soluble in small bulk by 4 grains of sodium citrate. The bismuth salt used by him is bismuth sodium tartrate which is generally given in 3 gram doses. Intramuscular injections were only employed in the initial experiments, and would not be suitable in so chronic a disease as leprosy, which requires very prolonged treatment.

#### SLOW HEART

SURGEON COMMANDER W. H. EDGIR R.N. writes. In connection with the question of slow heart action in athletes it may be of interest to state that I have constantly found a subnormal rate in the best Marathon runners in ships on which I have served. Four instances are present in my mind without reference to notes. Three were officers and one a private of marines. All were noted runners and capable of long sustained exertion and in all the pulse rate was between 54 and 64. I have come to regard the normally slowly acting heart as indicating special suitability for such exercises as running and boxing.

#### A DISCUSSION

MIR H. J. PATTERSON (London, W) writes. My attention has been called to a report of my annual hospital tea party in the *Daily News*. Although I was aware that the occasion was to be used for giving publicity to the hospital building fund I had no knowledge that personal allusions were to be made to myself. I much regret that in the report references were made for which I am in no way responsible and which are both unnecessary and undesirable.

#### VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges and of vacant resident and other appointments at hospitals will be found at pages 37, 38, 39, 42 and 43 of our advertisement columns and advertisements as to partnerships, assistantships and locumtenencies at pages 40 and 41. A short summary of vacant posts notified in the advertisement column appears in the *Supplement* at page 16.

## THE BRITISH MEDICAL JOURNAL · COMMEMORATIVE NUMBER

## An Address

ON

## THE OVERGROWTH OF SPECIALISM

DELIVERED TO THE ACADEMY OF MEDICINE IN TORONTO

BY

J. BASIL HALL, MCH, F.R.C.S.

PRESIDENT OF THE BRITISH MEDICAL ASSOCIATION, HO ORAP CONSULTING SURGEON, BRADFORD ROYAL INFIRMARY

I APPRECIATE very deeply the honour of being the first representative of the British Medical Association, since the affiliation between the British and the Canadian Medical Associations became an accomplished fact, to bring you our fraternal greeting and good wishes, and to address the members of our honoured profession in the great Dominion of Canada.

As I approached these shores I endeavoured to analyse my feelings. I found it difficult to realize that Ontario alone must be three or four times the size of the British Isles. As schoolboys we looked at our atlas and saw a map of England upon one page, and a map of North America upon another, but failed to grasp that vast difference of area of the two countries. Perhaps this was an early indication of our tendency in the old country to overestimate our own importance. Nevertheless, we do realize when we arrive at years of discretion that we are too self-centred, and we feel the necessity of cultivating a broader outlook, and a contact with the vigorous youth and newer views of our younger brothers.

As an illustration of our insular habit of mind, I would quote a passage from the writings of one of your own countrymen, a writer of whom you may be justly proud—Robert Service. The extract in which he gives us the rebuke we truly deserve is from his book *The Trail of Ninety-Eight*. The scene is laid in Dawson City, Yukon. A tall slim Englishman talking to the hero of the story, says:

How my old dad would stare if I could have him in Dawson City for a day! He would never be able to get things just in focus any more. He would be knocked clean off the pivot on which he has revolved these thirty years! Seems to me everyone is travelling on a pivot in the old country! It's no use trying to hammer it into their heads that there are more points of view than one! If you don't see things just as they see them, you are troubled with astigmatism!

Here is the opportunity, in your vast and wonderful country to readjust our convictions, and I thank you for helping to pull me off my pivot, and giving me the opportunity of seeing things from a new viewpoint.

Just as I was leaving the old country, the Council of the Royal College of Surgeons of England conferred upon me the honour of electing me a Fellow of their College. It is an honour of which I feel very proud, and I am deeply sensible of the distinction which it gives to me. My pleasure, however, has been very especially enhanced by the fact that I am sharing that honour with a Canadian, Professor Prunty of Toronto. I wish to extend to him my very hearty congratulations upon this recognition of his professional career, and to you, also, because he is one of your representatives in the great field of surgical science. I am sure you will forgive my insular prejudice when I say that I believe that it is one of the greatest surgical honours which can fall to the lot of any one of us, and in the years to come I shall always remember with much pride that my name had been associated with his.

## THE NARROW SPHERE

Your President has proposed to me that I should say something to-night about some views which I recently expressed in my Presidential Address at the Annual Meeting of the British Medical Association. On that occasion I suggested that the modern development of specialism is becoming so great and so absorbing that we are in danger of losing sight of the value of that wisdom which can only be obtained by a laborious study extended over much wider fields.

Specialism has become a necessity in our modern scheme of medical practice, but surely it behooves us to be careful lest our profession becomes nothing more than a community

of craftsmen, each in his own water-tight compartment with little or no general knowledge of the problems which lie outside it. There is a growing tendency—I am speaking of England—to think that special practice confines a man's usefulness in life to one narrow sphere. It is said not infrequently, that a specialist is an individual who knows everything about his own particular subject, but nothing about anything else. That definition may be only a cynical gibe, but I cannot help thinking that it might become a sober truth, and I would urge that the attainment of a high degree of any ability can only be reached by those who realize that wide general knowledge must be the foundation upon which all professional eminence can be built. To be content to learn one thing, and one thing only, is surely a poor ambition. It may bring wealth and worldly success, but it very rarely brings real greatness. "Everything of something but something of everything" is such a motto which all of us should adopt.

In military service or in a great hospital, where large numbers of patients have to be looked after, work is essential. The cure of the patients is a matter of mass production. It is the only method by which a great output can be accomplished. We have learned that lesson from the great commercial enterprises in the world. There are thousands of human beings to-day who spend their lives in producing one important particular detail in the mechanism of some machine, or some process of manufacture. I have personal acquaintance with a man who earns a very handsome living in such an occupation. He can merit well his work by a thousandth of an inch, but take him away from his one special employment, and you find him the dullest creature imaginable.

In the great iron and steel works in the city in which I was born there is a small group of men who earn large salaries by controlling the steam hammers which forge the wheels of locomotives and so forth. It is a great specialism, a craft which only a few possess. There appears to be a peculiar genius for this work, and I am told that it sometimes descends from father to son. The craftsmanship which these men display is wonderful, but take them away from their narrow specialism and you will find them very ordinary beings devoid of any interest in the progress of knowledge outside their own sphere.

Not very long ago I met a personal acquaintance who is a great expert in the textile world. His name is known in America, Australia, and many other countries. He had been spending a fortnight away from home, and I asked him how he had enjoyed his holiday. He said it had been very dull. He had just wandered about looking into the shop windows and reckoning up the cost of production of the materials displayed!

Specialism may be a great art, but it may be very soul-destroying. It may bring great wealth and notoriety, but it is a poor thing to live for, itself alone.

## JOHN HUNTER: A CONTRAST

A few months ago I enjoyed the privilege of attending the Hunterian Festival at the Royal College of Surgeons of England, and witnessed the large gathering of nobility, aristocracy and drink in solemn silence to the immortal memory of John Hunter—an annual tribute which has been paid to his name for a hundred years. John Hunter was the very antithesis of modern specialism, a man who never neglected the opportunity to study any single object in nature lest he might miss some fragment of useful knowledge. What a wonderful life his was! He was a great surgeon, but surgery was only a very small item in an existence devoted

to the study of every problem in nature. Hunter began his dissections and preparation of museum specimens when he was 30 years of age. He died when he was 65 years old but during those intervening, thirty-five years he dissected and mounted upwards of five hundred specimens, illustrating the anatomy of innumerable types of invertebrate and vertebrate life, and he wrote manuscript descriptions of most of what he had done. During those thirty-five years he worked unceasingly to solve every problem in the animal and vegetable world, and his classical operation for incision remains to this day as one of the most perfect deductions from scientific observation applied to a practical use.

Stephen Paget, in his *Life of John Hunter*, reproduces one of his letters, written to a friend in Africa a few months before his death:

"There could be no better example than this letter of the vehement energy of Hunter's life. In his old age, full of suffering, overworked, and close to death, he was yet writing, to Africa for swallows, ostrich eggs, a crane, cuckoos, a young lion, everything connected with the bee tribe, chamæleons and any other beast or bird."

While he was thus intensely intrigued with a human desire for general knowledge, he was Surgeon General to the Army, Inspector-General of Hospitals, Surgeon to St. George's Hospital, Surgeon Extraordinary to the King, and busily engaged in a great consulting surgical practice in London.

#### THE WIDER OUTLOOK

At the same festival, when I listened to the speech of the President, Sir John Blund Sutton, a speech full of wit, and a versatility which betokened a lifelong devotion not merely to the specialism of abdominal surgery, but to the study of comparative anatomy and zoology and the whole life history of mankind, I realized that his specialism had only played a very small part in placing him in the proud position he occupies to day. A great surgeon undoubtedly, but something much more than that—a man of wide scientific general knowledge, acquired by an endless study of human and animal life.

Only a few weeks later I was present at the funeral service of Sir Thomas Clifford Allbutt, Regius Professor of Physic in the University of Cambridge who died in his eighty-ninth year, a great scholar, and full of honours. He began his career as a classical scholar at King's College, Cambridge, and subsequently obtained first-class honours in natural science. Throughout his long life he never ceased to interest himself in any subject which might promote general knowledge. He introduced the clinical thermometer, which is used to day throughout the whole world. In 1871 he emphasized the value of the ophthalmoscope in the diagnosis of cerebral and renal disease. In 1873 he read before the Royal Society his paper on the effects of exercise upon bodily temperature. He subsequently edited a *System of Medicine*, which is one of which the medical literature in any language might be justly proud, and his work upon blood pressure, and the effect of over-existence upon the heart, is of great scientific value. It has been truly said of him that he was a charming speaker and a graceful writer. Faults of literary expression and logical arrangement vexed his soul. Truly a great physician, but something much more than that—a great scholar and scientist, and a very perfect English gentleman.

Is there any need for me to recall the life-work of such scientific giants as Pasteur, Lord Lister, or Sir William MacEwen? Do we not remember them as great men, who toiled unceasingly to promote general knowledge? Great men who required profound wisdom in an unlimited field of study, never doubting that every fragment of general knowledge would find its place in our scientific progress. Not so very long before the late Sir William MacEwen's death I was talking to him about the growth and shedding of the antlers of deer, a subject in which we were both interested, and one upon which he wrote a most absorbing book. Long after it has been forgotten that MacEwen introduced osteotomy to cure genu valgum that book will remain as a record of truth scientific research. Do any of us to day know anything about Lord Lister as a surgical "specialist"? His work as an operating surgeon is forgotten in the light of his labours in the wider fields of his researches. As an artist he is already forgotten, but as a scientific worker his name lives for ever.

#### WISDOM OR TECHNIQUE?

Is the modern trend of medical practice likely to produce such men as I have mentioned—men who were not interested in specialism but who were interested in the whole of life, whose mental activities were directed towards a synthesis of observation and research? Is it not possible that we are all specializing too much and reducing individual usefulness to very narrow limits. The human body is a complex structure composed of many organs, but there is a vital interdependence among them, which is essential for the maintenance of the whole. It is really desirable that every man should train himself to combine his knowledge to only one narrow branch of medicine or surgery, and believe that a perfect technique can accomplish everything.

The President of the Medical Society of London recently touched for the accuracy of the following anecdote:

A patient, worried with abdominal pain and obsessed with the popular dread of appendicitis, consulted a specialist who removed the appendix. The pain remained and she applied to a generalist who removed the right ovary. The pain remained and she applied to someone who had a great reputation for gastric surgery and she submitted to a gastro-enterostomy. But the pain remained. Nothing daunted she went to one whom I may describe as a general surgeon. He opened the abdomen but said that he felt so much which wanted rectifying that he closed it again without doing anything. She has now been restored to good health by a little more moral influence, and the sound knowledge of the nature of her doctor.

No man can become a good surgeon unless he is first a good physician. That saying is as true to day as when Sir William MacEwen first spoke it, and special knowledge and technique must always be subservient to the wisdom which can only be acquired by a wide study of human—yes, and animal—life. A man may be a perfect surgical artist, but never a great surgeon, unless he learns that even the most perfect technique is no excuse for bad judgement and lack of wisdom.

#### OPERATIONS OR SUCCESS?

At the risk of becoming unpopular amongst my younger brethren, I am going to say that I am afraid that we are producing a generation of operators, and not surgeons. With the advent of perfect asepsis the respect for operative intervention has almost ceased to exist. Moreover it has become the fashion to advocate the adoption of more and more radical procedures, in place of those which have given excellent results in the past. It is no longer sufficient to remove a patient's gall stones—his gall bladder must be removed as well. Gastro-enterostomy is being condemned as insufficient for simple gastric ulcer. A partial gastrectomy is now the operation of choice. If I remember rightly, this operation was first urged upon the ground that cancer is so often gift upon long standing simple ulcer, and I believe the risk of malignant incidence was placed at something more than 50 per cent. I have been at some pains to try to find a definite reason for this alarming statement, because I know that the occurrence of cancer after gastro-enterostomy for supposed simple ulcer is quite a rare event. Either the ulcers are only rarely malignant, therefore, or else gastro-enterostomy cures cancer. Latterly, however, the advocates of the more radical treatment have shifted their ground, and it is now stated that my lesser procedure than gastrectomy fails to cure. I suppose my experience of gastro-enterostomy may be regarded as small, because I have not to perform my thousands of operations. Nevertheless, I can lay claim to some hundreds. Perhaps I have been especially favoured by fortune, but I do know that gastro-enterostomy for simple ulcer has been very successful in my hands so much so that I could not possibly advocate the removal of half the stomach on account of a hypothetical risk of subsequent development of malignant disease. The same argument applies to cholecystectomy rather than cholecystotomy. I have performed some hundreds of the latter, but I cannot trace any case in which cancer developed subsequently, and I know from long observation that the risk of recurrence of gall stones is practically non-existent, so long as the cholecystotomy has been adequately performed. It has also been urged that total rather than subtotal hysterectomy should be practised for uterine fibroid, in order to prevent the possibility of the subsequent development of cancer in the cervix if it is left

behind. I recently inquired into the after-history of 250 cases of subtotal hysterectomy, but failed to find a single case of this unfortunate development. Incidentally, however, I learnt of a case of cancer in the vagina, which was said to have developed in the scar following a total hysterectomy. I commend that to all ardent advocates of extreme radical measures.

#### THE STRAM-HAMMER AND THE NUT

When I was a very small boy I was taken to a great exhibition in the Old Cloth Hall in Leeds. It was not long after Nasmyth had invented the steam-hammer and I still remember watching a man regulating a model of that wonderful invention. He was cracking Breckon nuts with it! I was too young at that time to appreciate the wonderful scientific accuracy of the machine, but I do remember thinking that I could crack them equally well with my teeth.

What is the real reason for this modern desire to adopt extreme measures? It is the love of something new, the love of a great idea, and—yes, I am afraid that I must also add—the ambition for the notoriety of specialism. Specialism is the lay public conceives it—a marvellous gift which enables a man to do something bigger, and incidentally more expensive, than his neighbour. The aseptic principle is a priceless asset in modern surgery, but I would ask you seriously to consider whether the modern ritual is not being overdone. It is not easy to draw the line between reasonable and extravagant methods, but such there is much in the surgical practice of to-day which is purely theatrical. Moreover, our concentration upon technique is deadening our sense of the supreme importance of cultivating clinical wisdom and judgement, the shrewd estimate of the vital capacity of our patient, and the great principle that we should never forget that the greatest artist is he who does the least possible to secure the desired end.

#### THE ART OF SURGERY

The art of painting and the art of surgery are very similar. There are artists who produce pictures by a few bold strokes of the brush or pencil. Their work captures the imagination and it lives. There is also the artist who produces a picture full of minute detail. It is very beautiful and perfect, but before long it begins to pall, and sooner or later it ceases to attract. So is it with the art of surgery. The surgeon who can grasp essentials, and who is gifted with "vision," because he has viewed Nature from a broad standpoint, lives in the memory of future generations. His work remains because he has studied the great essentials of life. The other obtains a passing notoriety on account of his perfect technique. It is all very pretty, and attracts the eye for the moment, but it lacks that sterling quality which marks real genius. Genius is not a heaven-sent gift. It is the infinite capacity for work—a capacity for using our brains in the study of everything which enters into our existence.

If I may make an appeal to the embryo surgeons of to-day, I would beg them not to be narrow in their ambitions. I would ask them not to be counting up the worldly wealth that specialism may bring, but remember that the passing of an examination, however high its standard may be, and a year or two of special experience will never relieve greatness. Theatrical display of elaborate technique, and the noisy advertisement of the latest methods, will obtain notoriety, but chain them to a life of comparatively joyless work. I would tell them that while it is a great thing to be able to do something better than anyone else, it is a much greater thing to be known as a great scientific worker, who can bring to bear upon his special craft a knowledge of human nature and all those attributes which make men truly great. I would ask them to realize that if they work for the love of working, in the first place, to work for the advancement of knowledge and the universal benefit of mankind they will obtain a great recognition and an ultimate worldly success. I would commend to them the words of Thoreau when he says: "If a man advances confidently in the direction of his dreams, and endeavours to live the life which he has imagined, he will meet with a success unexpected in common hours."

#### A MEMORY OF ST GEORGE'S DAY

As I came to you across the sea, little more than half-way I recollected that it was the eve of St George's Day—St George, the patron saint of England—and my mind went back ten years to that twenty-second day of April in the year 1915, when Falkenhayn, the German commander, launched on the battlefields of France, before Ypres his first poison gas attack—that abomination which violated all moral codes, and to which our enemy resorted in order to break our line by torture when he could not break it by overcoming our courage. Ypres, the gateway to the northern coast of France, was in due danger of falling before the enemy. Great Britain was threatened with starvation, the British Empire with ruin and the whole world with catastrophe. When England was in such desperate straits, when the best French division of seasoned Africans, which formed part of the fighting line, broke and retreated in torture and terror, who was it who stood fast and held the enemy back for nearly two whole days under the most appalling conditions ever experienced by any fighting force? It was the First Division of Canadian Volunteers, consisting of the Second Brigade under Brigadier Currie and the Third Brigade under Brigadier Turner. Can the old country ever forget the debt she owes to those men, or to those under General Alderson? Can we possibly forget such individual heroes as Major Knipfpatrick, who led the Fighting Tenth of Toronto, or Captain Straight, who by his courage and self-sacrifice inspired heroes to still greater efforts? In the story as written by Edward Wright we read:

'For a whole week the Canadians held the line that saved the Empire! When the main British relief came up at last by forced marches and went through the German barrage to take over the Canadian position there were scarcely more than two thousand Canadians remaining out of the old division of twelve thousand strong! The British cheered themselves hoarse as they gripped the hands of those newly made veterans whenever they got in touch with them. Canadians! Canadians! That was the British greeting when the weary, staggering, ragged two thousand went back through the German barrage to their rest billets!'

Another writer says

England has a thousand years of heroes before her eyes and she thinks of them with pride. Canada has made her great tradition suddenly! Canada has become a great nation great in territory, great in the boundless wealth of her cornfields, she only needed one thing—the glow of a great tradition.

Now I quote again from your Canadian poet, Robert Service, some lines from "The Younger Son," written before the war:

If you leave the gloom of London and you seek a distant land  
Where all except the flag is strange and new  
There's a bronzed and stalwart fellow who will grip you by the hand

And greet you with a welcome warm and true  
For he's your younger brother, the one you sent away  
Because there wasn't room for him at home  
And now he's quite contented and he's glad he didn't stay  
And he's building Britain's greatness o'er the foam

You will find him toiling, toiling in the north and in the west  
A child of nature, fearless, frank and free  
And the warmest heart that beats for you is beating in his breast

And he sends you loyal greetings o'er the sea

Then with the voice of the prophet he loses his poem with the lines

You've a brother in the army and another in the Church

One of you is a diplomatic swell

You've had the pick of everything and left him in the lurch

And yet I think he's doing very well

I'm sure his life is happy and he doesn't envy yours

I know he loves the land his pluck has won

And I fancy in the years unborn while England's fame endures

She will come to bless with pride—THE YOUNGER SON!

Gentlemen, we have come to bless with pride the Younger Son. Canada has now a great tradition. The men of Canada, the brave men of Canada, who went out into the great spaces of the earth and made them fruitful, crossed the sea to us in our hour of need and brought with them to Europe that priceless thing which lifts men to the height of heroes, and brings them very near to God. Once, at least in the great war you saved the British Empire and its Allies, and you are bound to us for ever with bonds of gratitude and affection.

## SOME MEDICAL ASPECTS OF HOLIDAYS\*

BY

SIR HUMPHRY ROLLESTON, BART, K C B, M D, Hon D Sc Oxon,  
D C L, LL D,

REGIUS PROFESSOR OF PHYSIC IN THE UNIVERSITY OF CAMBRIDGE PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON

*The Need of a Holiday*

THOUGH bank holidays are comparatively modern inventions, dating from Lord Aberg's Act of 1871, holidays and saints' days are very ancient institutions, so that in Plantagenet and Tudor times the routine of labour was probably more interrupted than in the nineteenth century. But the prolonged summer holiday has now become a much more established article of faith than it was fifty or sixty years ago—long after railways made travelling comparatively easy. Many causes for this change of custom have been suggested, such as mere fashion and imitation, the increased rate and stress of living, of which each successive generation rather boastfully grumbles, and, of course, the explanation, beloved of the *laudator temporis acti*, that the present race has become degenerate and less hardy than its predecessors.

In an interesting paper in the second volume (1924) of *Reports of the St Andrews Institute for Clinical Research*, Professor P T Herring explains "the Law of Fluctuation"—namely, that the constituent units of the body tissues are constantly varying between the two conditions of complete activity and complete rest, and that this mechanism prevents undue fatigue and its bad effects—this law being a necessary sequel to that of Keith Lucas's "all or nothing" response of nerve and muscle. Further, the graded response of a muscle as a whole is due to varying numbers of its units taking part in the response. What is true of the part is, *mutatis mutandis*, true of the whole, and the new law of fluctuation expresses in physiological terms the old ideas of rhythm and alternating phases of activity and repose. The momentary systoles and diastoles of the heart, the diurnal periods of wakefulness and sleep, and the annual holiday are illustrations of the same sequence. But just as the "all or nothing" law applies to units, so do the cardiac relaxations and the night's rest concern the shorter periods of man's life. The taking of holidays or relatively prolonged periods of cessation from work is on rather a different plane and is not of universal application, for those who do no work obviously cannot, by definition, have a holiday; work and holidays are the natural complements of each other, and there should not be any workers without their holidays, it has indeed, been said that overwork is no more meritorious than overeating or any other form of excess.

It would be interesting to attempt an estimate of the value of a reasonable yearly holiday in terms of health and longevity, by comparing those who have worked hard and taken an annual holiday with those who have toiled without a real break. General impression would unhesitatingly lead to the conclusion that constant work without a proper respite for repair must favour early senility. But in marshalling the evidence from individual examples of these two classes of workers other factors must be taken into account, long and healthy life depends to a great extent on a wise selection of parents for hereditary may counteract many sins against the laws of physiological righteousness; thus, as regards longevity, the average duration of life in one of a number of persons, both of whose parents reached the age of 80, was twenty years higher than in another series in which the parents died under 60 years of age (vide Raymond Pearl!), a regular holiday may not be adopted until a warning of ill health or a nervous breakdown has made precautions imperative, and a complete life-history, especially the incidence of infectious diseases, must be available. Examples of teachers, colleagues, or others who have ordered their lives on one or other of these lines will no doubt occur to you, so I shall mention two examples only of former leaders of our profession. Sir James Paget

(1814-1899) did without a real holiday for fifteen years (1845-1860) during his hard struggle as a young surgeon-pathologist, this, of course, was long before he "learned the misery of making only £4,000 a year" (eventually he earned £10,000 for some years). He had pneumonia six times between 1851 and 1870, a severe illness from post-mortem infection in 1871, at the close of his long life became, as his philosophically recorded, less and less able to do what he would, and died with "signs of congestion of the lungs." He had the advantage of a long-lived family behind him. Sir Henry Holland (1788-1873), whose span of life was the same, early determined never to allow his income from practice to exceed £5,000 a year, and to spend two months every year in travel, this he did for nearly sixty years (1814-1873), and, like Sir Thomas Browne, died on his birthday, two days after attending the trial of Marshal Bazaine in Paris, being ill for three days in all.

It must sometimes happen that a holiday is unconsciously taken just in time to prevent a breakdown or the onset of an infection such as tuberculosis, and it would be interesting to speculate on the frequency of aborted disease. The lowered resistance which was just about to allow infection to occur is braced up by the good conditions, and infection either does not make a start, or, if it has already taken root, is nipped in the bud or becomes latent.

While fully endorsing the physical and psychical need for a holiday in others, some seniors must admit that they have lost the keen zest of their earlier days to be off for a complete change, and that they no longer count the days before its advent with the same pleasant anticipation as in the past. Age has added inertia, a clinging to the home comforts, and a dislike to face the ills they know not of in unfamiliar surroundings. They no longer have the desire

"To burst all links of habit—there to wander far away  
On from island unto island at the gateways of the day"

Such men may no doubt plead that their lives are not like those of most other medical men, not confined to monotonous routine, but varied by different forms of mental activity and their professional occupations diversified by official and public duties. In fact, like some contributors to *Who's Who*, they would subscribe "Work" as their recreation. There may be much argument in this contention from the mental point of view, but it does not provide for hygienic repair and fortification.

Some people never take a holiday and yet seem to get on well. A medical man told me that for twenty years he had never left London, except for professional reasons, and that by walking five or more miles every day he kept in good health, and I know another member of our profession whose experience is the same after ten years. These are, of course, exceptions, and their example is not without danger for the rank and file. Years ago a physician whom I found ill in town in August quoted Sir James Paget's record as a reason for his own self-denial, it certainly seemed that his early death from pneumonia, a few years later, may have been due to lowered vitality induced by following too closely in the footsteps of the great. Comparison between those who "live" and take holidays, sometimes spent at spas undergoing "cures" on the one hand, and those who take exercise but no holidays, though otherwise obeying the dictates they preach, on the other hand, might show but little difference on the whole, and so account for the apparent success of the medical man who never left London for twenty years.

The holiday requirements at different ages of life deserve some attention, the young especially when rapidly growing, need much more rest and holidays than is perhaps generally recognized, and certainly more than adults, this is a point which the harassed parent of a large family does

not in any gratefully acknowledge. It is, however, hard to find any physiological reason for the discrepancy between the length of the terms at Oxford and Cambridge and those of students in the medical schools of London. As age advances and habits gain a firmer hold, the demand for holidays becomes less obvious or at least less clamorous. But perhaps the best test as to the suitability of a holiday to the various ages is the simple therapeutic one, so to speak, and to conclude that as long as a person really enjoys a holiday, he or she is of the right age for that form of holiday.

The time of year for a holiday is for many of us largely determined by the general lull which accompanies the absence of others during August and September; it is true that the younger generation, who act as substitutes and pickers up of the rather elusive crumbs left by the absentees, go away earlier or later. But otherwise a holiday at unaccustomed times may be considered to favour of mild eccentricity or impaired health, neither of which is a recommendation or advertisement of solid worth. From the hygienic point of view there is much in favour of splitting up the annual holiday allowance into two or three parts, but each of these should be a complete holiday. Some people are slow starters and take about two weeks to get into the holiday frame of mind and body, and therefore need a more generous reaction than others.

There are the two alternatives (1) of returning year after year to the same favourite spot, which has become a second home with well proved sources of pleasure and satisfaction, and (2) of going to a new place every year so as to expand our limited knowledge of the world and to avoid the disappointment from less favourable circumstances than on the previous occasion. On general grounds it would appear that the plan of a fresh place each year is more suitable for the young and energetic, who are more able to find manifold outlets for their bursting vigour, and that those approaching "the sear, the yellow leaf" will be happier in the haven that they know suits them.

The length of a holiday, like its nature, varies with the individual, although six to eight weeks is the ideal; it may be suggested that just as the necessary hours of sleep show considerable variation, so do the holiday requirements of different individuals. Holidays may be divided into several categories, such as the complete, the partial, the educational, the therapeutic, and the failures. The conception of holidays includes two rather different aspects, which, however, overlap—first, that of recreation, and secondly, that of rest and repair.

1 Recreation consists in change, distraction, and activity of a pleasant nature in a direction other than that of ordinary routine life. It is mainly a psychological remedy, as shown by the good effect of switching off from one line of work to another, thus relieving one part of the mind while healthily exercising another, and possibly, though here we are on rather uncertain ground, exerting a beneficial influence on the corresponding areas of the subconscious. As Sir James Paget<sup>1</sup> pointed out, there is a remarkable contrast between man and other animals in the matter of recreation—for except in the case of young animals, man alone refreshes himself by seeking fresh forms of activity.

The methods of recreation are various: it may be intellectual or physical, indoor or outdoor, and must vary with the individual's temperament and tastes. Although recreation essentially produces a mental rather than a physical change, it may be effected by physical means; thus it is perhaps most rapidly attained by fast or active motion—for example, running, riding, motoring, or flying, though the last is a more or less intelligent anticipation of what will probably hold good for the future, walking, which, at any rate in streets, does not exclude the companionship of black cabs, is therefore far inferior to bicycling or lawn tennis. As a complete change from the strain of life, medical men not uncommonly seek a holiday in stinking, shooting, or fishing, while others, tired of percussing the chest, obtain relief in driving golf balls over or even into bunkers. "A doctor's holiday" was the subject of the late Dr. W. M. Ord's oration to the Medical Society of London in 1884, in which, while admitting a

diversity of tastes, he inclined, apparently from his own hobbies, to the distractions provided by natural history or literature. But though it would be attractive to formulate the most suitable forms of distraction for the various professions and vocations, it is probably wiser to be content with the conclusion that it should be so different from ordinary life that the individual forgets his occupation and habits in becoming a natural man. A sedentary worker's recreation should be muscular exercise in which the mental processes, though no longer the sole form of activity, are in quite a different line, exercise is therefore a specially valuable form of recreation, as it influences both the body and the mind. In a rather analogous sense reading or writing as a form of recreation for the manual worker, while altering the mental outlook, also provides bodily rest, but it should be noted that the total physical benefit must vary according as an open air worker rests in clean air or in a contaminated atmosphere, such as that of a cinema or concert hall, or, again, according as a worker in a badly ventilated workshop takes his time off in a garden or in a stuffy room. On the other hand, an intellectual worker who seeks recreation in bridge or the theatre is thus benefiting his mind without any accompanying physical advantage. An important factor in recreation is the faculty of keeping thought-tight compartments in the mind whereby attention can at once and completely be switched off from one subject to another—a faculty said to have been possessed by Gladstone and Kitchener. Recreation is of course fully recognized in the ordinary working life of everyone, and the degree to which it is put into practice no doubt has a bearing on the need for a prolonged holiday; some maniaacs have more will than recreation, and vice versa, and, other things being equal, the need for prolonged holiday will vary directly.

2 The factor of rest and repair is part of the rhythm of life—as shown in the frequent distoles of the heart and the night's sleep, but a holiday differs from these in being at much longer and often irregular intervals, and in being under the control of the individual's discretion or indiscretion. What should be, but is not invariably, a form of holiday occurring at short and regular intervals—one day in seven days holiday—is the weekly Sabbath ordained in the Scriptures which has been expanded into the modern week-end habit, thus enabling the conscientious week-ender to obtain 104 days of freedom during the 365 days or the year. A well arranged week-end habit may thus to some extent obviate a prolonged holiday of six to eight weeks in the year, in the now far-off eighties a friend of mine, who was often chided on account of his rather frequent disappearance from the hospital where he was house surgeon, retorted "It is all very fine for you to laugh at me, but I keep fit, whereas you get knocked up and then have to be away for two or three weeks." But the week-end is more often a diversion or distraction than a rest, and sometimes, though a change, is not devoid of fatigue. It is perhaps only a natural outcome of the cry of "the wear and tear of modern life" that the *Daily Mail* some years ago made the suggestion that if one day a week were spent in bed, the medical profession would have much less to do than is at present necessary. A few people indeed begin the regular summer holiday by going to bed for a week, but usually these are neurosisthenics and are or think that they are, on the verge of a breakdown when the date of their annual holiday comes round.

The rest factor in a holiday, ordinarily so called, nearly always concerns mental rather than physical activity—in fact increased exercise is usually recognized as an essential feature of holidays. An important point is to secure complete change of environment and mental atmosphere, to get away from him- or herself, to pass a sponge over the mental slate and so wash off the dust and irritants of ordinary existence; for this reason a holiday at home has distinct drawbacks. As a first step it may be necessary to have a cessation of activity before passing from one state of life to another however different, but this again had better, because more easily, be taken away from rather than at home.

In order to secure a more complete change of mental atmosphere there is much to be said for a holiday apart

from the family or usual associates, at any rate in the case of some persons. Sir Henry Holland, who probably got the most possible out of his long life, though he was not an epoch-making pioneer in medical science, went abroad alone yearly for two months during fifty years, and depended for social intercourse on chance meetings on his journey. Respite from soul-destroying routine and worry should be continuous and complete during the holiday, but often men who obey the call for fresh air, change of scene, and exercise, keep in touch with their profession or business while staying in this country. Again, men who live most of the year in town for the sake of their work may take a house in the country for the holiday months of August and September, and come to town once or twice a week to keep an eye on their work, they thus slack off but do not leave off their usual routine, while getting more into the fresh air, but they do not get an entirely new mental atmosphere—they change their physical but not their psychical environment, in fact, such a holiday is partial instead of being complete, it is more like a glorified and oft-repeated week-end and approaches the life of a stockbroker who lives at Brighton and comes up to Change so many days a week. The physical health may benefit, but the mental groove is still between the same lines. There is therefore an advantage in taking holidays abroad, where calls, consultations, and certificates are not so likely to reach their intended recipient and as a rule correspondents cease from troubling. Much wisdom lurks in the interesting announcement in the social columns of the press that "Mr. and Mrs. Chamber-Brown have gone abroad, and letters will not be forwarded." Foreign travel also involves a more complete change of scene and of mental attitude, whereby the individual loses sight of self among the innumerable new objects of interest, in spite of Horace's dictum, "Coelum non animus mutant qui trans mare eurrunt." A sea voyage has similar advantages, and further secures more isolation, which, however, is now not quite so complete as in the pre wireless days. In addition it has the virtue of enforcing rest, which may not be an accompaniment of foreign travel and the itch to see as many capitals, pictures, views, and sights in the least possible time. Such a Continental scramble may, indeed, leave the traveller with an indigestion of impressions and ideas, and more fatigued in body than when he started out, so that he really requires a lotus-eater's rest on his home coming. A holiday abroad has, of course, a wide application as an education, and its value may be augmented by careful preparation in acquiring a knowledge of the country, its history and its language, it thus forms what might be classified as the educational holiday.

#### *The Educational and Utilitarian Holiday*

While the health-bringing influence of a holiday depends on fresh air, sun, and change of environment, the good effects on the mind are due to occupation in new directions—such as natural history, science, literature, art, and archaeology. A holiday may therefore promote general culture and broader interests, and thus initiate a hobby, and so prove a valuable asset by providing recreation for the remainder of the year. This, indeed, is particularly true with regard to holidays spent abroad, with a foreign language, scenery, architecture, and manners to stimulate the visitor. Reference may be made to the question whether, as medical men, we should, when passing through great medical centres, be better advised to avoid a return, even for a short space to a professional atmosphere, or whether we should be wise to take an opportunity of widening our knowledge and sympathies by visiting the medical school and seeing the buildings, laboratories, libraries, clinics, hospital facilities, and the prominent professors and teachers. Acquaintance thus made with places, personalities, and ideas will help to correct the all too common tendency to insularity and a narrow outlook which unconsciously grows and gains on us with the passing years. Though to do so is certainly open to the condemnation of its resemblance to a business man's holiday, there is a distinct difference between a flying visit to a medical school while happening to pass through a large town and on the other hand, going abroad to do a definite piece of work.

Does not the benefit obtained from such an incidental visit more than counterbalance any drawbacks due to its shoddy character? Medical congresses abroad may be regarded as in much the same category as the passing visit to a medical centre, for though professional in name the general atmosphere is in reality much of the holiday picnic, they are a means of obtaining a welcome change of surroundings and combining a medium of work with pleasant travel and the opportunity of making fresh friends.

#### *Holiday Failures*

Indian natives who have sailed for but not succeeded in obtaining a B A degree sometimes advertise themselves as "failed B As," and in like manner there are holidays that fail, though they are not correspondingly a matter for boasting. A man may go away to the seaside and uncomfortable lodgings to be cramped up with his family, whose healthy noise and motousness—especially when, as in some Augusts, "the moon is smiling every day"—gets on his nerves the whole time, and from which he has no excuse, such as his work or real diversion, to justify his escape. In this plight a man may count the days to his release from the discomforts and boredom of a so-called holiday. A holiday without his family is sometimes the best for a man of the irritable genius type. As regards physical health, the conditions at home may be superior or inferior to those encountered on a holiday, especially abroad, and the adverse conditions when away may be little more than counteracted by the increased amount of time spent in the open air and healthy exercise.

The most serious failure is that of the perpetual holiday often anticipated vaguely without any thought, much less realization, of its actual contingencies throughout a strenuous career, a successful business man retires or a professional man is placed on the shelf by the age limit, and what does he find? Unless blessed with wide interests or mercifully aimed with some engrossing hobbies, the long-expected fruit of delight may turn to ashes on his lips, and he experiences what Bernard Shaw calls "the horror of the perpetual holiday", he will then itch for real work, and even go so far as to return in a subordinate position in his own business, or, if no deliverance in the form of public work comes to the rescue, proceeds to deteriorate both in body and mind.

An aspect of holidays that should be mentioned with due circumspection is the effect on some members of the family of the holidays of other members. In probably not very rare instances parents suffer from the strain entailed by the holidays and proper entertainment of their children, a quiet, orderly household, with plenty of elbow room for those of mature years, suddenly becomes crowded with exuberant youth, full of restless energy and not unaccompanied by audible signs of exuberant enjoyment or excessive expostulation. The middle-aged, already "set" in their habits and somewhat intolerant of noise, often find it hard, though it is undoubtedly salutary, to become young, and when there are extraneous sources of anxiety may abandon any such attempt and be left with nerves jangled and irritable.

#### *Diseases due to Holidays*

Although a thorough change is an essential part of a complete holiday, there are possible abuses in the method of making this change, and from the practical, not from the cynical, point of view, a few remarks may be devoted to 'the diseases due to holidays'. They may be divided into (1) those occurring during absence from home, and definitely due to the unusual conditions and manner of life, (2) those arising after the holiday, but traceable to its conditions or influence.

1. It is unnecessary to discuss constipation due to interrupted habits caused by the exigencies of travel, food poisoning resulting from experiments in unaccustomed articles of diet, water-borne diseases, such as enteric fever, or other endemic infections, such as malaria and Malta fever, except to intimate that due precautions should be taken with regard to diet and the choice of the foreign resort and to local conditions at the time of the visit, such as the endemic prevalence of influenza, of enteric fever—

which obviously suggests T A B vaccination before leaving home—the presence of mosquitos and of endemic malaria. Just as I was revising this paper I came on an article by V. Y. in the *New Statesman* (1925, vol. 529) entitled "DANGER!" and beginning, "Holidays are for the robust," and humorously exaggerating the risks. Accidents such as sprains do not need any reference, but the risk of cardiovascular strain must not be forgotten. Thus a middle-aged man after ten months or more of sedentary life suddenly, without any training, launches out into active exercise such as he was accustomed to take thirty years ago, for example, he at once starts climbing in the Alps, and may come seriously to grief by dilating his heart. Unwanted sea-bathing and swimming may prove too much for a man whose heart and arteries have insidiously undergone the changes of arteriosclerosis. Some of the bathing fatalities ascribed to cramp may really be angina pectoris.

2. *Diseases arising after the Holiday but traceable to its influence*—A drawback to travelling, especially for long distances abroad, is the risk of picking up infection—flu, influenza, catarrhal, or tonsillar—from railway carriages and sleeping cars. It is disappointing after an invigorating holiday, such as at a Swiss winter resort, to develop a cold or sore throat directly after return, and thus to realize that much of at least the physical benefit of the change has been neutralized. This is therefore an argument for motoring abroad, provided the weather is suitable, in preference to railway trains.

Another occasional sequence to a holiday is that the acquired immunity, due to unconscious intermittent vaccination with the micro-organisms of dirt, catarrhis, lapses in the pure air of a holiday, and that a cold or sore throat asserts its right to afflict the holiday-maker so soon after his return that the sunburn on his face has not as yet vanished, if the explanation of the lapse of acquired immunity is correct, it would be natural to expect that a long holiday would be more likely than a short one to be followed by this mishap. It has been thought that those engaged in *post-nortem* work are more prone after a holiday than at other times to become infected and suffer from boils or sores. Sir James Paget<sup>1</sup> held this view, and in writing on a surgeon's freedom from infection while daily exposed to pus and his susceptibility when no longer thus protected, quotes E. Symes Thompson's<sup>2</sup> experience that while engaged in doing necropsies he escaped infection, but on returning from a holiday to this work a scratch on his finger was followed by severe illness.

#### Advice to Patients

Where, when, and how to take a holiday to the best advantage is a subject on which most people feel that, as on a number of other subjects, they are authorities, and are more inclined to impart than to follow advice. Though medical help is commonly sought as to the best place to undergo a cure for some morbid condition or tendency, and a holiday or rest from their labours is often prescribed by medical practitioners as an essential of treatment, ordinary persons seldom take expert opinion about their holidays, except from travelling agencies. The healthy boy or young man regards a holiday as merely a return to a state of freedom from the toil and the restrictions of civilized and artificial life, and would consider it absurd to dream of taking advice or of making any special preparations for a return to a state of natural and simple existence. But however it may be with them, their elders would often gain by adopting the humble course of asking advice.

National health is attracting ever-increasing attention, and many improved methods have been instituted among the directions in which a useful advance might possibly be made is the more careful choice and arrangements for holiday-making. Those seeking advice should be impressed with the really serious importance of selecting the right kind of holiday and place, and further with the need for self-education in arriving at a proper decision. Just like any other course of action in life, a satisfactory holiday demands some trouble, though it might be urged that some of those who are in the position of advisers in this matter are themselves cranks and should practise in conformity with their preaching. The ordinary healthy person leaves the selection

of the place of his yearly holiday largely to chance, whereas skilled medical advice might effect a good deal in obviating failure in holidays. A sedentary worker often suddenly starts on active exercise at the very beginning of the holiday without any preparation in the way of training the heart and muscles for the increased strain thrown upon them. In the young there is so much reserve power that real harm seldom results from such rapid transition from solely intellectual to mainly physical activity, though not uncommonly after a holiday full of unwonted exertion there is on returning to work a feeling of lowness and fatigue which takes a week or so to wear off. It need hardly be mentioned that after an infection, such as influenza, a young patient must be cautioned against starting active exercise with too much enthusiasm, on account of the risk of myocardial strain. But as the years glide by and middle age becomes established, the margin of reserve narrows, and the holiday-maker is surprised to find himself suddenly pulled up by cardiac pain or distress on returning to the athletic habits of his youth. The risk of such an unpleasant experience should certainly be minimized by advice based on a medical stocktaking directed to consideration of the state of the blood pressure, heart, and arteries. A holiday should not be regarded in the light of an incident, such as an evening party, which can be embarked on without some measures of preparation, some time before setting off for a climbing expedition in Switzerland or stalling in Scotland, a course of walking, hopping, skipping, or training for the muscular and cardiovascular systems should be undertaken. Further, the week-ends might be utilized as trial trips. By such a course of training the risks of sudden strain should be eliminated. Patients with anaemia should be cautioned against taking much exercise, for clinically the importance of rest in bed for patients with grave anaemia is well recognized, and experimentally G. O. Brown found that after a long period of sedentary existence in cages, in which presumably little blood was being destroyed and made, dogs then exercised vigorously for several days showed temporarily a great decrease in the circulating haemoglobin and red blood corpuscles from increased mechanical haemolysis, the compensatory function of the bone marrow being caught napping. In dogs previously exercised, as in human athletes during training, no such anaemia results, and the general experience is that after short periods of exercise the haemoglobin and the red count are raised. In recommending a holiday to another attention must be directed to the physical condition and power, temperament, inclinations, and hobbies, and for successful advice personal knowledge of the individual and of places counts for much, for in unaccustomed holiday would be worse than useless. The worries attendant on a long journey, with the rush of getting off and the care of children and luggage, may be minimized if the anxious mother and the irritable father take a sedative dose of bromide to render them philosophic, cheerful, and less prone to a train headache.

Holidays are often taken at spas, and here the physical benefit which results, or should result, from the "cures" for some bodily disease or disorder, may be impeded or modified by the boredom and dislike of the place chosen by high authority for his victim. Therefore, in considering the course of action, the mental as well as the physical factors should be taken into account. The experienced knowledge of practitioners who, like the late Sir Hermann Weber, specialize in hyrology, climatology, and balneology, is a valuable supplement to the particular knowledge of the individual possessed by his medical attendant. A dance of over-fatigue and of overfeeding, which the stimulating air and interest may excite, should be insisted upon.

## A Lecture

ON

## THE PSYCHOLOGY OF ANIMALS SWALLOWED ALIVE.

DELIVERED AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND ON JUNE 5TH

BY

SIR JOHN BLAND SUTTON, Bt.,

PRESIDENT

Many discoveries and observations made by naturalists are of little interest to the public but animal psychology and vagaries of the human mind are interesting to all

When sitting in quiet contemplation digesting after dinner, with beneficent microbes hard at work within me, I sometimes wonder if animals who swallow their prey alive are worried by the aerobiotic efforts of victims trying to escape

The same idea must have occurred to many boys after reading the curious experience of Jonah, swallowed alive by a big fish and subsequently vomited upon the shore for his adventure. In Matthew's Gospel the creature that swallowed Jonah is called a whale. Matthew may have

been a good evangelist but not a naturalist. This is not surprising, for he was a customs officer under Herod the Tetrarch. There is a tradition that Jonah was the son of the widow of Zephath, Eliah restored him to life, and delivered him to his mother, saying, See, thy son liveth.

The story of Jonah and the whale has been the source of many quips. There is a misericorde in the stalls of Ripon Cathedral representing the prophet in the act of being swallowed by a whale—the mouth of the beast is well furnished with teeth—and another representing him emerging from the mouth of the whale (Fig 1). The verger supplies this pun. When Jonah felt himself in the power of the whale, he was down in the mouth and felt he was going to blubber!

The open mouth of a big whale may measure 20 ft in length, 15 ft in height, and 9 ft in width. Such a chamber would easily accommodate twenty Jonahs standing upright.

Many believe that the story of Jonah and the whale stands by itself, but the *Boston Post Boy*, October 14th, 1771, reports upon undoubted authority that an Edgartown whaling vessel, after striking a whale, had one of her boats bitten in two by the whale, and Marshall Jenkins, one of the crew, had been taken into the mouth of the whale, which had then smelt with him. On returning to the surface, the whale had ejected him on to the wreckage of the broken boat, much bruised but not seriously injured. The whale concerned in this exploit must have been a big sperm whale.

In old pictures representing the Jonah Miraculous the creature which swallowed the prophet is usually a whale with teeth, but among the beautiful stained glass windows in the Church of St John at Gouda there is one in which Jonah is shown full and immaculately clothed, walking out of the mouth of a huge cod-fish.

Sharks

Sharks are well known as formidable tyrants of the ocean, and their voracity is almost beyond belief, and sometimes ends in their own destruction.

The diodon, a curious fish not uncommon in tropical seas, is furnished with strong teeth which enable it to break off and crunch hundreds of coral on which it feeds, and its skin is beset with sharp spines. This fish has the power of inflating itself until it assumes the shape and size of a big bill, when inflated, the spines stand out like the quills of a porcupine, hence the popular name of the diodon is porcupine fish.

Durbin, in 1832, was on the *Beagle* in the South Atlantic when he became acquainted with this curious fish. On the authority of Dr Allan of Lorient, he states that big sharks swallow the porcupine fish, and has frequently found

it floating alive and distended in the stomach of a shark. On one occasion a porcupine fish swallowed by a shark had eaten its way out not only through the coats of the stomach, but through the walls of the body, and thus destroyed its captor. Darwin asks, Who would ever have imagined that a little soft fish could have destroyed the great and savage shark? The diodon inflates itself with air and water, which it expels with some force when it deflates. The jets of water must cause some curious ticklings to a shark with a lively diodon in its stomach!

No one need be sceptical in regard to a shark's ability to swallow a porcupine fish, or of difficulty in accommodating the fish when it reaches the stomach. Some idea of the gastric capacity of a shark may be gathered from the following evidence. Sir William Turner dissected a Greenland shark (*Lacnæus borealis*) nearly 12 ft long. Its voraciousness was revealed by the contents of the stomach: one cod fish and two salmon averaging 3 ft in length, nine haddock, a small skate, the carcass of a small porpoise without its head, and bits of blubber.

A remarkable example of the voracity of the tiger shark was reported by F. A. Mitchell-Hedges. A party of explorers, engaged in deep sea research in the Caribbean Sea, killed one of these ocean tyrants. This shark measured 17 ft in length, 9 ft in circumference, and weighed nearly 2,000 lb. Its stomach contained eighteen deep sea eel-fishes (21 in length), each weighing between 4 and 5 lb. Every one had been swallowed whole. It seems a vicious taste on the part of the shark to swallow these extraordinary creatures. They resemble animated coal-scuttles. The fish in this case is called a tiger-shark, not on account of fierceness or

rapacity, but for the mottled appearance of its skin. Lockwood, an American naturalist, studied the habits of king eels in 1870. In New Jersey they are used for feeding ponies and hogs, female eels are preferred. A female king eel may contain half a pint of eggs, they are like mustard seed, but of an ash green line. There is a belief that this diet makes poultry lay, fattens

FIG 2—Sperm whale and whalebone whale in outline to show the peculiarities of their heads (F. B. Hart)

fowls and hogs, but gives a shocking flavour to the flesh of both.

Things more curious than fishes are sometimes found in the stomach of a shark. In 1779 Michael Fitton, in charge of the tender of H.M.S. *Iberigenny*, cruising off

FIG. 3.—Showing porcupine fish (a) deflated and (b) inflated. When inflated it is as big as a coco-nut. (Günther)

St. Domingo, caught a large shark, which was hoisted on board the tender. Some seamen cut the head off the fish and cleaned the jaws, and others opened its maw, it contained "a parcel of papers tied up with string." The letters were of recent date, and Fitton had them dried on deck and read them. One of the letters related to a brig called the *Nancy*, which had been seized as a prize. The captain and the crew of the *Nancy* were tried and convicted with the aid of this letter in the Old Court House, Kingston. How this packet got into such a curious post-box is a matter for conjecture.

Lat and be eaten is the rule among fishes in the sea. Fishes not only eat each other but even their own off-

FIG. 4.—The black swallower (*Chasmodon nigrum*) a deep sea fish which swallowed a fish larger than itself. Half natural size. (Natural History Museum)

spring, and a few are so ravenous that they attack and swallow fishes bigger than themselves. The black-swallower (*Chasmodon nigrum*) lives at a great depth in the Atlantic Ocean, below 1,000 fathoms. There is an example in the Natural History Museum which was dredged at 1,500 fathoms, and it contains a dead fish bigger than itself (Fig. 4). The captured fish was clearly discernible through the tightly stretched belly when the fish came to hand. The black-swallower is clearly allied to cod-fishes, which are cannibalous, and is sometimes found floating dead on the surface of the ocean with a fish in its stomach. When a fish has been swallowed in such circumstances decompo-

sition outstrips digestion, and the generated gases cause the fish to rise so rapidly from the depths of the ocean that it is killed and floats on the surface. This may be regarded as a good example of post-mortem revenge.

#### In Ocean Crime

Most of the deep-sea fishes are pale green or blue when caught, but they turn rapidly black. Some are colourless and gelatinous, a few are silvery. In museums they are usually represented by models and these are usually black but their characters are blacker. The example of the

FIG. 5.—*Gigantura rostrata* 80 mm. long with a *Chaulichodus* 1-2 mm. long in its stomach (C. T. Pagan) and the head of *Chaulichodus* to show its teeth.

black-swallower has been in a measure eclipsed by an exploit of a deep-sea fish, *Gigantura* (Fig. 5) obtained in the Atlantic by the Dana Expedition (1920-22), and carefully described by Mr. C. Tate Regan. This fish lives at a depth of 500 metres. Its eyes are telescopic closely packed together, and directed forwards. It has a formidable dental armature—the teeth are slender, sharp, and depressible. In each jaw a pair of anterior canines directed forward are followed by a series of strong spaced teeth, with smaller teeth between them. The fish is precocious, and has a very capricious stomach. It is probably a lurking fish that steals upon its prey, aided by powers of vision beyond the ordinary.

In the "Dana" specimen the fish was 80 mm. long but neatly picked in its stomach there was a deep-sea fish, *Chaulichodus*, 140 mm. in length. *Chaulichodus* has a formidable dentition, and the *Gigantura* must have been desperately hungry to attack a fish twice its length and formidably armed with teeth. After an examination of the body of

FIG. 6.—The black fish (*Dallia pretorialis*) a fish found in Alaska its vitality is astonishing. (Turner)

the victim, Regan reconstructs the crime in this way. The *Chaulichodus* was seized by the middle, and was swallowed double until it reached the posterior end of the stomach when its head and tail still protruded from the mouth of its captor. These were then taken in and bent back until the whole fish, now doubly folded, was in the stomach of *Gigantura*. Digestion affected the part first swallowed where the fish has quite disappeared, exposing the vertebral column for a length of 18 mm. It seems horrible to be slowly digested alive!

The pike is the most voracious of freshwater fishes and consumes large quantities of food. Big pike will seize

rats, voles, and it is said they attack foxes and small dogs. They gorge each other occasionally with extreme thoughtlessness for their own safety. In 1880 Dr. Burton supplied Buckland with the following story: A boy saw in the Tweed near Kelso what he thought was a fish with a tail at each end of its body. He caught it and was astonished to find two pike, one of which was trying to gorge the other. They were alive, and he put them into a tub of water and parted them. As soon as they were separated the larger pike attempted to gorge the smaller. One weighed 3½ lb., the other 2½ lb. (Fig. 8).

Fishes are sometimes careful in what they attempt to swallow—probably from experience. A John Doiv, living in an aquarium with some fifteen spined sticklebacks, was foolish enough to swallow one. He swam around squirming as if he had gripes. After two minutes he vomited the spiny little fish, which seemed none the worse for its adventure and went back to the weeds apparently as unconcerned as if he had not been disturbed. Kingfishers are fond of the little fishes known as bull-heads, or miller's thumbs, but they are cautious in selecting their prey, for the big pectoral fins of these fishes may stick in their gullets. This is another form of retaliation. In musing on such events I think most will agree with Shakespeare:

The sense of death is most in apprehension,  
And the poor beetle that we tread upon,  
In corporal sufferance feels a pang  
As great as when a giant dies.

A live fish in an animal's stomach must cause some discomfort.

The black-fish (*Dallia pectoralis*, Fig. 6), discovered by L. M. Turner, lives in the sphagnum ponds and swamps of Alaska. These fishes exist in enormous numbers and are the chief food of the natives; they are caught in specially made baskets. Between May and December many tons of these fishes are taken to the villages as they are exposed to severe temperatures and cold wind. The mass of fish in each basket is frozen in a few minutes. When required they are chopped out with an axe. The vitality of these fishes is astonishing. They will remain in the grass baskets for weeks and then brought into the house and thawed out. They are quite lively. Dogs swallow them eagerly. The heat of the dog's stomach thaws the fish, and the movements of the revived fish soon cause the dog

to vomit it alive. The fish seems to be a long-suffering creature. What of the dog? We may say of our friend:

—He got rid of an ill-considered meal in a sagacious manner. Several varieties of our freshwater fishes bury themselves in the mud during the winter months. This is also true of frogs and toads, but they are not frozen.

In tropical countries some fishes bury themselves in the mud during the dry season. This summer aestivation is well illustrated by the mud fish of Uganda. The mud fish (*Protopterus*) abounds in the marshes around the Victoria Nyanza; it is a curious creature, and breathes by lungs and gills. This fish is eel-like in shape, and may attain a length of six feet. It is rapacious on worms, frogs, crustaceans, and its own kind. The cannibalistic instinct is so great that it is difficult to keep mud fishes in an aquarium, for they eat each other. In the hot season the marshes in which these fish live dry up, to meet this change they burrow into the mud, coil up at the bottom of the burrow, and surround themselves with a capsule of mucus secreted by the skin glands (Fig. 7). Sequestered in this way the fish breathe entirely by their lungs, half the year, and remain secluded in the marshes until the return of the rain. When the

mud fish adjusts itself to the cocoon, the flask-like cavity which contains it is closed by a perforated lid, the margin of the hole forms a funnel which leads to the lips of the fish. If a straw be gently passed down the funnel it will if alive utter a cry. The fish is so completely encased that it

may be dug up and transported anywhere. The Baganda call the mud fish, some natives regard it as a delicacy and keep it as a provision in elod. Some years ago a mud fish was brought in a elod to the Zoological Gardens, where it was released, and lived and thrived for three years.

#### Snakes and Frogs

As a rule people dislike snakes, but some snakes are harmless and can be easily tamed and allow themselves to be handled. Some snakes become affectionate in captivity but most are morose. Even a cobra may become a pet as in the case of the albino cobra caught by Mr. J. C. Roberts of Delhi. Albino snakes are rare, and in this instance Mr. Roberts is very

attached to this cobra, carrying it about everywhere with him and allowing it to careen him. The dislike to snakes may be in part due to the influence the

serpent creased over his. The serpent in this instance must have been a tree-snake, because in Milton's description it climbed the apple-tree. It was a snake that

'Led his credulous mother, to the Tree  
Of prohibition root of all our woe'

Snakes, especially cobras, are prominent in the Hindu Pantheon. There are many snake tales in Hindu religious writings, and Lama stories in which a prince accidentally swallows a snake which lives on his vitals.

It is impossible to comprehend reptilian psychology, Joan Procter has described a curious instance of a silver tree-snake fixating a lizard (Fig 9). The tongue of this snake is coloured in the same style as its head when the tongue is protruded through the rostral notch, with the lips closed, it appears to be a continuation of the snake's snout. She has seen a lizard watching the hovering tongue in perplexity, quite engrossed, and the snake staring at close range without stirring the usually swift and cautious prey. Miss Procter describes the effect of this "pulling faces" as really most arresting to witness.

It is easy to prove that the prey of constricting snakes are frequently swallowed alive and survive delivery by human agency.

Rudyard Kipling supplied me with the following incident. At Bateman's, in the county of Sussex, the gardener found a grass snake with a bulge in the belly, and promptly lapped off the snake's head, slit open its belly, and with a little help "a frog slid out head first, but alive." Rain was plentifully lubricated with silver, and on the ramp there were rails of two fangs. Otherwise no damage. The frog emitted a low croak as it was returned to a proper home among the lilies in the pond.

John Roscoe, missionary and ethnologist, while travelling from Uganda to Gondokoro, came across a snake engaged in swallowing a big frog. It was curious to watch the frog struggling to make its way down the snake's gullet, evidently thinking this the way of escape. A native killed the snake. Roscoe opened it and released the frog which sat blinking as though astonished to see the light again, and then jumped among the grass.

Tree-frogs are favourite food of snakes. They have pads on the ends of their fingers and toes. The skin covering the pads contains glands which secrete an adhesive fluid which enables the frog to stick on a slippery surface such as a leaf, they adhere as much by the belly as by their digits. Tree-frogs can jump, when the artist was engaged sketching the frog (Fig 10) he suddenly missed it and began hunting around. In despair he sat down and looked at the drawing. Suddenly he was astonished to hear "Eep, eep, eep," close to his ear, and felt something cold on his neck. To his astonishment the frog was sitting on his shoulder croaking agreeably and—criticizing the drawing!

Gardow, whose interest in amphibians and reptiles leads him to keep and tame frogs and snakes, considers the grass frog "a jolly and intelligent fellow."

We know little, and can only surmise in relation to reptile psychology, but I have heard of a psychologist who made an excellent use of a frog in the following circumstances.

A thin and foolish woman believed she had accidentally swallowed a frog and that her thinness was due to the frog eating the food in her stomach. In order to dispel the illusion the doctor gave the patient an emetic and during the vomiting he slipped a small frog into the basin. When the patient saw the frog her joy was great, but in a few minutes her depression returned. "Oh!" she exclaimed,

"I am sure this frog has left some young creature in my stomach." The doctor looked wise, pulled out his magnifying glass, and after critically examining the frog said unto the patient, "Fear not this frog has not left any froglet inside you. Behold, it is a male!" The patient was quite satisfied, became happy and in a few months was pained again. She was not a naturalist, and therefore ignorant of the fact that it is difficult to tell the sex of frogs by mere inspection except at the breeding season.

Miss Kingsley knew a witch doctor at Kincongo West Africa, who treated bewitched persons, and was successful in removing the witch with rubbings and an emetic. In the vomit he always found several lucky young crocodiles. Magic and mystery worthy of a conjurer!

#### Snake swallowing Snake

Deglutition in snakes is a remarkable process. These reptiles are carnivorous and as a rule take living prey. Many swallow the victim alive, some kill by constriction. Poisonous snakes kill small mammals, birds, and fishes almost instantaneously and swallow the prey at leisure. The progress of deglutition is often slow and laborious, and can be watched in a menagerie. A python twenty feet long can swallow a goat or a pig. In some countries (Congo Territory) when the natives find a python gorged with a pig they kill the python, release the pig, and then eat both the python and the pig.

In reptile houses the fondness of snakes for frogs is cleverly utilized. The king cobra eats snakes and disdains frogs. In England it is difficult to obtain grass snakes in winter; the keeper gives the grass snake a frog and then passes the frog-containing snake to the king cobra, who thus gets the captive frog as well as the snake. Even snakes can be tamed.

Cannibalism signifies the eating of human flesh by human beings; the term "cannibal" is often applied to animals which eat their own species. It is true that snakes swallow snake sometimes accidentally, sometimes intentionally. It occasionally happens in menageries that two snakes fasten on the prey and as neither is willing to let go its hold the stronger will engulf the prey and the snake which clings to it. Thus, in the well known case reported by Brittle, a big box eleven feet in length

fastened on a pigeon, a companion box nine feet in length also fastened on the pigeon. In the course of a night the larger box swallowed the pigeon and the box, and, what is more remarkable, it not only digested them but survived and twenty-eight days later took a pigeon. This was clearly an example of unintentional snake cannibalism.

The king-snakes (*Ophibolus*) common in the United States, Mexico, and Central America, are recognized cannibals. These pretty constricting snakes may attain a length of six feet; they are mild and inoffensive to man, allow themselves to be handled, and learn to recognize their keepers, and feed from their hands.

The king-snake is named from the fact that it is immune to snake poison, this reptile eats birds, lizards, and small mammals but prefers snakes, and even poisonous snakes. It is said that king-snakes will eat eels, probably mistaking them for snakes. They eat their own species. When animals are given them for food they get excited, and when several king-snakes live in the same compartment they are apt to attack and swallow each other. The liability to such accidents is well known, so that when king snakes, living in company, are supplied with frogs and mice, the keeper looks after them, because, if two snakes seize on the same prey,

FIG. 10.—Tree frog (*Hyla blanchetii*, Procter) showing pads on the tips of the fingers and toes. The first finger slightly longer than the second is used as a thumb in life.

## DIFFICULTIES IN THE DIAGNOSIS OF LEUKAEMIA

the stronger snake may, and probably will, engulf his opponent as well as the rat. It has happened that when a boa has engulfed a companion, the keepers have succeeded in withdrawing it by steady traction on their tails. Snakes have not only recovered after such an occurrence, but lived together in amity.

Snake swallowing by snakes was well known to the ancient Egyptians. When Moses and Aaron met the magicians in Pharaoh's court they knew the trick of making serpents become stiff rods, and when cast upon the ground Aaron's rod swallowed up the Egyptians' rods (Exod vii, 12).

Meditations on the psychology of the swallowed suggest that the animal world may be divided into swallows and the swallowed. A whale swallowed Jonah, but it is wiser for a man to swallow a whale than to swallow a hel

## DIFFICULTIES IN THE DIAGNOSIS OF LEUKAEMIA

BY

G LOVELL GULLAND, C M G, M D,

PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, PROFESSOR OF MEDICINE AND CLINICAL MEDICINE IN THE UNIVERSITY OF EDINBURGH

THE nomenclature of the leukemias is still in a fluid state, and the subject has been discussed elsewhere (Gulland and Goodall, *The Blood*, third edition, 1925, p 212). It seems desirable to keep the terminology as simple and yet as precise as possible, so we have adopted the terms "non-granular" and "granular" as the main subdivisions—the former including two acute forms, the myeloblastic and lymphatic, and the chronic lymphatic form, the latter the acute and chronic forms of myelocithaemia. The acute myeloblastic and lymphatic forms are probably the most common, but many of them are certainly not diagnosed, and in any case their duration is short. The chronic forms last for years, and are practically always recognized sooner or later, and bulk therefore more largely in the mind of the practitioner. I shall accordingly deal first with them.

## CHRONIC GRANULAR LEUKAEMIA

In the chronic granular leukemias the disease is so insidious in onset that the first thing to attract attention, if the patient comes under observation before the anaemia is marked, is usually the enlarged spleen. It is surprising how often there seems to be difficulty in determining whether it is the spleen which is enlarged or some neighbouring organ. I remember a febrile leukæmia in a woman, many years ago, which was sent into a surgical ward as a cellulitis of the abdominal wall. The surgeon was clear that this was a wrong diagnosis, but thought the spleen was a tumour of one of the pelvic organs, and transferred the case to a gynaecologist, who was certain that the tumour was not pelvic, but refused to determine its nature. Of course a blood examination settled the matter. Enlarged spleens in leukæmia may and do wander all over the abdomen, and might be taken for any organ in turn, according to their temporary position. Complicated small enlargements are often taken for tumours of the splenic flexure, and several times patients have come to me who had been treated after barium meals and enemas. The true nature of the mass was only suspected when the passage was found normal. It often takes much more than a roentgen examination to settle whether a given enlargement is spleen or kidney. Neither organ, when enlarged, invariably retains its typical shape, and when enlarged, invariably becomes very superficial, and the colon which crosses it may be loaded or empty, and there are many tracts, and not easily made out, and there are many cases of kidney swellings with blocked ureters in which the urine gives no help. Some cases have required air enemata, metrical catheterization, full blood examination, etc., before their nature was definitely determined.

To-day I saw a man whose right kidney was removed some years ago for calculi associated with constant pain and haemorrhage and the formation of a large tumour. At operation the kidney was found to be cystic in addition, and it was suspected that the left kidney was in the

same state. It has steadily enlarged and the diagnosis is undoubtedly correct. Since my last examination the kidney had increased considerably in size, and so altered in shape that it looked at first as if a splenic enlargement was superadded to that of the kidney. The converse of this case was supplied some time ago by a very uræmic woman with great digestive disturbance, who came to me with the diagnosis of cancer of the stomach. Her left kidney had been removed for pyonephrosis many years before, and the spleen, which was only moderately enlarged, lay close forward as usual, but, in the recumbent position, lay well back in the left flank and under the ribs, and had to be looked for. She had advanced granular leukæmia.

The blood in these cases when they first come under observation is almost invariably so typical that no error is possible if the attendant examines it or causes it to be examined. The initial count, however, even with a markedly enlarged spleen, may vary greatly—from 500,000 or more to 42,000, 35,000, and 22,000, which are the lowest I have seen. The blood in these cases with low counts is nevertheless quite typical. The only likelihood of error is the presence of a febrile complication, which is subnormal causes a drop in the white count to normal or remission figures, or the rare possibility of a spontaneous remission. But even then abnormal cells will almost always be present which will give the necessary indication, though they are sometimes few in number.

The effect of irradiation on the blood is by no means uniform and is difficult to forecast. The rule, of course, is a marked diminution in total numbers with a speed of drop in the immature granular cells, but there may be no effect at all. Generally speaking, this refractory state is more common in cases that have previously been irradiated, but it does occur in cases treated thus for the first time as soon as the disease was diagnosed, and, on the other hand, some cases will respond repeatedly to irradiation until the course is cut short by some complication. It is important to remember that the effect of irradiation persists for months sometimes, and that there may be a progressive diminution in the number of the leucocytes. For this reason one usually stops irradiation when the white count has reached 20,000, as there will probably be a further drop when treatment has ceased. The case mentioned above with an initial count of 22,000 was treated by rays to the long bones for special reasons. This was stopped when the count fell to 12,000 three months ago, and the count is now about 5,000 with practically normal proportions. In the last films no immature cells of any kind could be found, the usual excess of basophils had disappeared, and the film looked like an ordinary mild secondary anaemia with a slight leucopenia. After prolonged search one normoblast was found. If this film had been examined by someone unacquainted with the history of the case, diagnosis would have been impossible.

Radiation may apparently, however, sometimes produce

a condition closely resembling myelocysthaemia. Some years ago, in November, I saw a lady whose breast had been removed for cancer a year before. She had been treated by x-rays from that time till August. She was anaemic—small ends of both clavicles, the liver was down to the umbilicus and apparently nodular, and the spleen was palpable. Cancerized encystomatosis was the probable diagnosis, but the examination of the blood introduced a doubt. The white cells were 12,800, there were numerous neutrophil myelocytes and some myeloblasts, and, further, there were nearly 7,000 nucleated red cells to the cubic millimetre, about half of which were normoblasts, the rest megaloblasts. A second count, a week later, gave 9,400 whites with the same picture as before and the same number and proportion of nucleated reds. The blood picture was that of an acute myelocysthaemia, the eosinophil and basophil excess at the chronic type was absent. The alternative diagnosis was widespread metastatic cancer in the bone marrow, which may produce a blood picture resembling leukaemia, and which was obviously more likely in this case. The lady returned to London and died in Westminster Hospital about six weeks later. Dr. Hildred Carhill kindly wrote to me about the subsequent history. A fortnight after I saw her the white count was 8,000—neutrophil polymorphs 59 per cent, lymphocytes of all forms 40 per cent, eosinophils 1 per cent, no myelocytes, and no nucleated reds. The spleen had returned to normal in size. A later count was almost exactly similar. At the post-mortem examination almost all the cells were found in the liver and ovaries, but not in the bones examined, and indeed, in view of the later counts, it was not to be expected. One is almost driven to the conclusion that my findings represented an erythroblastic and leucoblastic crisis resulting from the prolonged anaemia.

#### CHRONIC LYMPHATIC LEUKAEMIA

Chronic non-granular or lymphatic leukaemia is much rarer than the granular form, and less dangerous to life as a whole. I have seen cases, ultimately fatal, in which the first glandular enlargement—which had never disappeared—had been noticed eighteen and twenty years either respectively. Both these patients had been in fair health until a year or two before the end. In such cases the process almost certainly starts in the lymphatic glands and gradually involves one group after another, as these the process almost certainly starts in the lymphatic glands and gradually involves one group after another, becomes completely involved. There is no reason why the process should not start in any bit of lymphatic tissue in the body but a start in such extraglandular lymphatic tissue as the follicles in the bronchi or the intestine would mean an almost immediate spread to glands, and an apparent glandular onset. In cases where the process starts outside the bone marrow, the chronicity or acuteness of the individual case seems to depend entirely on the period when the marrow becomes involved, and on the rate at which the marrow space is filled by lymphocytes. When this occurs the marrow is available for erythroblast proliferation and in anaemia which is practically aplastic in character the results are severe as in the acute myeloblastic and lymphatic forms in which the starting point is in the marrow itself. Nor is the tendency to haemorrhage so great on the whole as in the chronic myelocysthaemias. The chronic lymphatic cases are much more apt to die from the pressure effects of the glands, which are so much more uniformly enlarged in this form than in any other from the tendency to thrombosis of veins, and from the interference with function due to the infiltration of vital organs. As internal glands may sometimes be the first affected, pressure effects may occur early, and may cause puzzling clinical pictures until the blood is examined. An interesting example of this difficulty presented itself about eighteen months ago.

A lady who had complained of shortness of breath for about six weeks developed pleurisy with effusion without rise of temperature, about a fortnight before I saw her. The effusion had to be tapped several times before it ultimately settled down. Her doctor, who had gone over all the usual possible causes without result, examined her blood and found a great excess of lymphocytes. My first count

was red cells 4,700,000, haemoglobin 75 per cent, white cells 55,800. Of the whites 91 per cent were lymphocytes, degenerated lymphocytes and there were no myeloblasts. There was no enlargement of liver or spleen and enlarged gland could be felt above the umbilicus and the right clavicle from elsewhere, but the veins in front of the chest were unduly prominent. The single gland was evidently in offshoot from a nodular mass. During the next six months while she was under observation the white cells fluctuated between 35,000 and 85,000, the proportions remained much as in the original films. The left lung was slightly dull all over, with diminished expansion. This was evidently a pleurisy resulting from the presence of a mass of leucocytes in the mediastinum. The patient is now well symptomatically, except for some weakness and shortness of breath on exertion, no other glands have appeared.

As these cases advance the white count usually rises slowly, and may reach a very high figure. In March of this year a man was seen who had noticed some enlarged glands at the back of the neck in 1918. Other groups were gradually involved, and at his first visit all the external glands were greatly enlarged and the spleen reached the umbilicus. A diagnosis of lymphadenoma had been made but the blood had never been examined until he gave up his work elsewhere and settled in Edinburgh. My first count gave red cells 2,680,000, haemoglobin 50 per cent, and in the counting chamber the white cells were so closely packed together that the ruled lines could not be seen. When I had drawn the blood up to the figure 1 in the pipette it gave the astonishing figure of 2,224,000, which, so far as I have been able to find, is the highest count of white cells recorded in any condition. The films bore out this count: the white cells seemed quite as numerous as the red, and were practically all small lymphocytes. The patient was treated with arsenic. Six weeks later the glands had gone down to about a quarter of their former size—very often a general improvement in health. He had thrombosis of the veins of the left leg and generalized oedema with pleural effusion, he ultimately died suddenly. On this occasion the red count and haemoglobin were rather better than before, the white cells had fallen to 1,132,000, and were again practically all small lymphocytes. One neutrophil polymorph was seen in counting 500 cells. Though he had never been robust he had been able to carry on office work until a few months before his death.

#### ACUTE MYELOBLASTIC AND LYMPHATIC LEUKAEMIAS

Every physician is familiar with the hopelessness and tragic rapidity of the acute myeloblastic and lymphatic leukaemias. It has happened to me to see a patient who was well until a certain Saturday to make the diagnosis on the following Tuesday when he had a count of 10,000 white cells, and to see him die on the Friday with a count of 20,000. Recently the opportunity presented itself of observing throughout a case very nearly as rapid. The first recognizable symptom was epistaxis on the 20th of the month, there was haemorrhage later into the skin and from the kidney and bowel, and the termination was profuse haematemesis on the 29th. The red count was at first 4,800,000, haemoglobin 65 per cent. It showed a steady fall and on the 29th was 2,400,000, haemoglobin 42 per cent. This is typical of these cases. The rate is a gradual drop in red cells with a rising colour index—in this case from 0.6 to 0.87. If the case lasts long enough it is not uncommon to get a colour index above unity, and to find normoblasts as well as normoblasts in the blood. Another point of importance is the progressive diminution in the number of blood plates. The white count ran 9,300, 6,400, 10,400, 15,700. At first the polymorphs were 30 per cent, and at the end 10 per cent, at first also there were some neutrophil myelocytes and some eosinophils and basophils. The percentage of non-granular cells was about 60 in the first films of which 48 were myeloblasts. At the end the non-granular percentage had risen to 88, of which 65 were myeloblasts.

On analysing my cases it is evident that the acuteness of

the disease is nearly proportional to the percentage of myeloblasts and to the rate at which the percentage increases. Cases in which the true lymphocyte proportion remains high last much longer. Most of the cases of acute leukaemia are easy to diagnose, because though the leucocyte increase is small, there is usually an increase, and, except for the foregoing consideration, it matters little whether the excess is lymphocyte, myeloblast, myelocyte, or promyelocyte, or a mixture. The important point is the diminution of polymorphs and the great excess of cells with a round nucleus. With an ordinary Jenner stain all the forms except the myelocytes look very much alike, and special staining methods have to be used to differentiate them. But there is a group of cases which are very doubtful. Two recent examples will illustrate it.

The first was a lady of 52 who had suffered from melancholia for ten months. For a fortnight the temperature had been high. No physical signs of any kind were present to account for this. The white reaction was negative to typhoid and the paratyphoid fevers, and no enteric bacilli were found in the stools. There was no enlargement of external glands, the spleen dullness reached the border of the ribs, but the spleen could not be felt definitely. The white count was only 1,900. Not a single polymorph was seen, about 35 per cent of the whites were myeloblasts, the remainder lymphocytes. She died two days later.

The second was a man of 50 who was first seen because of an irregular pneumonia which had lasted for about a week. The white cells were 16,300 with only 70 per cent of polymorphs and no glycogen reaction. The comparatively low polymorph percentage made me suspicious that there was some condition behind the pneumonia. A week later the lung had cleared up and the white count had fallen to 7,600: polymorphs 54 per cent, lymphocytes 40 per cent, eosinophils 3 per cent, myelocytes 2 per cent, myeloblasts 1 per cent and a few normoblasts fairly numerous blood plates. A week later he was definitely anaemic: red cells 3,250,000, haemoglobin 50 per cent, white cells 6,000—polymorphs 22 per cent, lymphocytes 66 per cent, myeloblasts 8 per cent, myelocytes 2 per cent, eosinophils 2 per cent, a few normoblasts, blood plates few and large. Three weeks later (intermediate counts are omitted) the red cells numbered 1,000,000, haemoglobin 18 per cent, white cells 5,900—polymorphs 18 per cent, lymphocytes 66 per cent, myeloblasts 12 per cent, myelocytes 4 per cent, with numerous normoblasts, there were no megakaryoblasts. There was no enlargement of spleen or glands throughout and no haemorrhages—only progressive weakness as the main symptom.

How are we to class these cases in the absence of post-mortem evidence? In spite of the low white counts I can only regard them as acute leukaemias—the first probably mainly myeloblastic, the second mainly lymphatic. The differential count must be the criterion. The whole question, however, depends on the significance of myeloblasts occurring in the circulating blood—a subject too large for discussion here. It is to be hoped that some better method of differentiating myeloblasts in films than either Jenner-Giemsa or the oxydase reaction will be discovered and that some haematologist will undertake the embryological studies necessary to clear up our views of the phylogenetic relationship of these cells.

In connexion with the type of case just described, it will be realized that difficulty will sometimes arise in the diagnosis from pernicious anaemia, and this for two reasons—first, the not infrequent occurrence of a colour index of unity or above it in myeloblastic leukaemia and secondly, the high non-granular percentage in the differential count of pernicious anaemias. The first difficulty only arises if we are to regard cases of the type quoted as leukaemias, for increase of the white count is the rule in myeloblastic leukaemias, but is very rare in pernicious anaemia, and when it does occur is always a polymorph leucocytosis, and not a non-granular increase. The second difficulty may be illustrated by the following recent case. A man of 65 who showed all the characteristic signs and symptoms of pernicious anaemia had a red count of 1,500,000, haemoglobin 35 per cent, white cells 3,500, of the latter 84 per cent were lymphocytes, the remainder polymorphs. There were no myeloblasts. At first sight such a percentage makes one think of an acute lymphatic leukaemia, especially if the whites have not been counted, but the actual number of lymphocytes in the cubic millimetre is not really greatly increased. If we assume that the normal number of white cells per cubic millimetre is 7,000, of which polymorphs are 70 and lymphocytes 30 per cent, the actual number of polymorphs in the cubic millimetre will be 4,900 and of lymphocytes 2,100, while in the case quoted the lymphocytes are 2,940—not an overwhelming increase.

We are far too apt to use the percentages of the differential count, it would be wiser and would avoid misconceptions if we always quoted the absolute numbers of the different cells in the cubic millimetre. One safeguard in this bit of diagnosis is that myeloblasts are rare in pernicious anaemia, though they do occasionally appear. I have never seen them in sufficient number to cause error.

The difficulty of diagnosis between lymphatic leukaemia and glandular fever may be a very real one. Most cases of the latter disease are of short duration and do not present much difficulty, but in a recent case the temperature lasted for eight weeks and the enlargement of the glands nearly as long. The patient was a woman of 22, the enlarged glands were widely distributed on both sides of the neck but not elsewhere, there was slight enlargement of the spleen. The red side of the blood was a mild chlorosis, the red cells dropped slightly as the disease progressed. The first white count taken by her doctor, about a fortnight after the onset, was 16,000—polymorphs 14 per cent, lymphocytes 86 per cent. My first count, a few days later, was 12,000—polymorphs 26 per cent, lymphocytes 74 per cent, but in addition there were a great many degenerated lymphocytes with smeared nuclei, practically all the lymphocytes were "large." No myeloblasts were seen. Thereafter the count gradually dropped as the temperature fell and the glands diminished in size, and it has now for some weeks run about 3,000, with such proportions: polymorphs 44 per cent, lymphocytes (almost all small) 54 per cent, eosinophils and basophils 1 per cent each—that is to say, the blood picture is now that of a chlorosis with the polymorph leucopenia so common in that condition. Before I saw the patient the doctor had given the diagnosis as lymphatic leukaemia—a very natural conclusion on the evidence. I have heard of glandular fevers lasting a longer time, but have never seen one.

#### "A SARCOMA OF THE LEUCOCYTES"

No more need be said about the essential nature of leukaemia than that I regard it as a sarcoma of the leucocytes. The assumption that the disease is a sarcomatosis, however, only removes the difficulty a stage further back, and the problem is bound up with the question of what influence it is which in health keeps the normal number of leucocytes in the blood within such narrow limits. We know that the action of parasites, using the term in its widest sense to include bacterial and other organisms, can powerfully alter the count in disease in both positive and negative directions, that the proteins of food and probably other proteins and many other substances have definite actions. Does the interference of an infinite variety of substances keep the balance in health, and, if so, does it act directly on the bone marrow and the blood, or through the medium of some other organ? These questions require a definite answer before we shall progress much further in the understanding of leucocyte problems.

It is very striking when one examines the marrow of a myeloblastic leukaemic patient who has died with a count of, say, 20,000, to find all the tissue one can examine packed with myeloblasts to the practical exclusion of every other type of cell. The wonder is, not that the leucocyte count is increased, but that it is not vastly higher. One cannot resist the feeling that the excess of cells in the blood is there rather as an overflow than in response to any active call upon the marrow cells. Obviously the condition is widely present in the marrow before there is any evidence in the blood of its existence. A leucocytosis responding to an organismal infection occurs practically at once, and the marrow gets under way immediately, but never goes beyond the amount of hypertrophy required in each special instance. A leukaemia progresses in the marrow more or less steadily, in the acute cases progressively till death occurs. We do not know whether the spontaneous remissions which sometimes occur in the blood picture of the chronic leukaemias correspond to a real alteration in the condition of the marrow, if they do they are not more frequent than the retrogressive changes that occur in some tumours. It is well to keep an open mind but until further research throws fresh light on the disease the neoplastic theory of its causation is the most logical and satisfying explanation.

## Historical Notes

ON

## THE SITE OF THE ASSOCIATION'S NEW HOUSE

BY

E. MUIRHEAD LITTLE, F.R.C.S.

THE British Medical Association is but following the example of the Dukes of Bedford in moving from the Strand to Bloomsbury, for in 1704 the Russells left their great house near Covent Garden, and occupied their new mansion on the north side of Bloomsbury, or, as it was then called, Southampton Square. At that time there was open country at the back of the new house, and the view of Hampstead and Highgate from the garden was much admired. Compared with the Strand, the northern part of Bloomsbury has but a short history, and even compared with the southern part, which includes Bloomsbury and Bedford Squares, it is modern Bloomsbury Square was inhabited by distinguished persons as long ago as the seventeenth century, whereas Russell Square and the streets and squares to the north and west of it were not built until the beginning of the nineteenth century. In the map of London and Westminster by John Cary, published in 1801, most of them are represented as planned but not yet built, and only a few buildings on the north eastern side of Tavistock Square are represented as already existing.\* Among these was

Tavistock House, the site of which is now covered by the New House of the Association.

In the Crace collection of maps in the British Museum there is a "Plan of the Estate of the Duke of Bedford laid out for Building by James Burton, 1806," in which Tavistock House is indicated as already standing in its own grounds at the back of the Tavistock Square buildings already referred to (see Fig 1). Through the kindness of Lieut.-Colonel Evelyn Gordon, the present agent to the Duke of Bedford, we learn that this house was built by James Burton in the years 1795-96, and it appears in various maps published in the last

century as "Tavistock House." It faced north-west, having a road in front of it, which afterwards became known as Tavistock Place North. This road appears to have been at one time continuous with Crescent Place, which leads to the once notorious Burton Crescent, now called Cartwright Gardens. It was, however, never a thoroughfare, being blocked by railings and a strip of garden at the north eastern end, where Burton Street now is, and by railings and gates a short distance from the Tavistock Square frontage. The topography is shown with some approach to accuracy in Cruchley's New Plan of London (Fig 2). This is said to be "improved to 1833," though it is hardly up to date as regards Tavistock House, which was enlarged and divided in 1825, but it shows the garden ground at the back of the house which was coterminous, as it is to-day, with the garden of a detached house in Tavistock Place. This house (which, like Tavistock House, is given

an erroneous ground plan) was of some celebrity. To this dwelling that remarkable stockbroker and man of science, Francis Baily, four times President of the Royal Astronomical Society, removed when he retired from business, and here, during many years, he carried out numerous scientific experiments, culminating in 1841 in the determination of the density and weight of the earth. His public services in connexion with astronomy and exact mensuration were immense, and Sir John Herschel did not exaggerate when he stated that his revision of the star catalogues alone entitled him to rank amongst the greatest benefactors to astronomy. Baily died in 1844, without any royal recognition of his immense services, despite the fact that he had greatly benefited the navy by his successful efforts to reform the *Nautical Almanac*. The house was afterwards occupied, till 1877, by the well known architect, Sir Matthew Digby Wyatt.

The James Burton above mentioned was a very important and well known personage a hundred years ago, he was a speculative builder and contractor who built nearly all the newer streets and squares which cover the northern part of the Bedford Estate. Dobie quotes a statement to the effect that in forty years Burton had built 2,336 buildings in various parts of London, including Regent Street and the houses of Regent's Park, where he was associated with Nash. He became a very rich man, but in his later years he lost a great deal of his wealth in the development of St Leonards-on-Sea, to which new resort he ran a service of stage coaches. His son, Decimus Burton, is better known to fame as the designer of the arch at Constitution Hill (but not of the Duke of Wellington's statue, which once stood thereon), and of many country houses and villas. Burton's design for the arch included a quidring, perhaps such as that by another hand which has since been substituted for the equestrian statue of the Duke. He was so much chagrined by the erection of the latter that he made provision in his will for the payment of £2,000 to the Government if it would remove that monstrosity.

The original Tavistock House was occupied by various tenants, until in 1812 James Peery acquired and lived in it. He was a well known journalist and reformer, who was born at Aberdeen, and originally wrote his name Peire. Having failed as an actor he became a reporter and regular contributor to the *General Advertiser*. As such he reported the trials of Admirals Keppel and Palliser. He planned and edited the *European Magazine*, and afterwards, as editor of the *Gazetteer*, introduced the system of employing a succession of reporters for the parliamentary debates. In 1789 Peery and a friend bought the *Morning Chronicle*, which soon became the leading organ of the Whig party. Lamb, Hazlitt, Coleridge, and Campbell all contributed to it. Like other Liberal journalists in the days of revolution in France, Peery did not escape prosecutions and imprisonment, but he emerged from them triumphant and they only increased his fame. In 1792, for having printed an advertisement of the address passed at the meeting of the Society for Political Information, held at Derby five months before, he was charged with having printed and published a seditious libel. The proceedings dragged on for a year, but finally Peery was acquitted. Five years later he was in trouble with the House of Lords for sarcastically suggesting that "the dresses of the opera dancers are regulated there." For this awful crime he got three months in

FIG 1—Part of the plan of the estate of the Duke of Bedford laid out for building by James Burton 1806. Baily's house is shown standing back from The Parade (now called Tavistock Place). The Skimmers Land is still held by the City company of that name as trustees for Tonbridge School. Crace Collection Portfolio A.V. No 18.

FIG 2—The neighbourhood of Tavistock House from Cruchley's New Plan of London Improved to 1833.

\*Strictly speaking the Association's New House is not in Bloomsbury proper: it is in the Parish and Metropolitan Borough of St Pancras and not in the Borough of Holborn to which Bloomsbury belongs. The northern boundary of the ancient Manor or Burgh of the family of the 1st Lord later known as Bloomsbury and included in the old Parish of St Giles in the Fields lies to the south east of Tavistock Square and Place.

Newgate, where he held levees of his friends, and where presents of game and other luxuries poured in upon him. In 1809 he was once more in the dock charged with the heinous offence of reprinting the malicious suggestion of the Hunts in the *Examiner*, that the successor of George III would have "the finest opportunity of becoming nobly popular." This time he was quickly pronounced not guilty. Perry had a country house at Wimbledon, and his neighbour, Lord Nelson, stood godfather to his daughter George Robins (*vide infra*) drew up the catalogue for the sale of furniture at the Wimbledon house in 1822.

Perry died in December, 1821, and a few years later one Thomas Hill, who had acquired the lease, obtained permission from the Duke of Bedford to convert the main house into three separate residences, it appears from the plans that two wings were added to the original house, one westward and one eastward, at an approximate cost of £5,875. Thus it is seen that the original Tavistock House had become Bedford House, and the name of Tavistock was transferred to an entirely new house adjoining it on the south-west. In 1842 the executors of the late Thomas Hill assigned the remainder of their interest to George Henry Robins. This was the celebrated auctioneer whose name was a household word in the middle of the last century, and whose hyperbolic and flowery descriptions of the properties which he sold became proverbial. In the *Ingoldsby Legend*, "The Babes in the Wood," he who would ill treat children is wined.

Be sure he who does such base things  
Will ne'er stuff Conscience's clown  
His riches will make themselves wings  
And his property come to the humble!  
Then He—and not those he deceives  
Will have no cause for sighings and sobings  
When he finds him self smother'd with leaves  
(Of fat catalogues) heap'd up by Robins!

Robins became very rich and gave much in charity, and thus he has a special interest for us as a supporter of hospitals. On one occasion at Newgate he made a collection for the Royal Sanatorium Infirmary, holding a plate in the street outside the church. For this act of begging he was taken into custody as a rogue and vagabond and this embryo flag dragged ended in his being prosecuted before the magistrates at Dover. But no evidence was offered and at Wandstone Assizes he brought in action against the magistrates and was awarded £50 damages.

His three houses were at this time mentioned in the *Standard* as being for 1857 they appear as Nos 1, 2 and 3 Tavistock Villas. They were also known in the estate lists as 1, 2 and 3 Tavistock Place North, but in 1845 the two end houses were there referred to as Tavistock and Russell House.

#### CHARLES DICKENS

In 1851 Charles Dickens took Tavistock House then and for many years previous to the residence of his friend Frank

Stone, A.R.A. "In 1852 the original lease was surrendered and new leases granted by the Duke, as follows. The most eastern house (afterwards called Russell House) to Frank Stone, the central one (afterwards Bedford House) to John Bate Cudde, and the most western one (afterwards Tavistock House) to Charles Dickens."

Thus the once youthful reporter and contributor to the *Morning Chronicle* had come to live, not in the same house, but in one of the same name and next door to that in which the celebrated proprietor and editor of the paper had lived and entertained the men and women of light and leading

of his day. In the *Chronicle* most of the *Sketches by Boz* had first appeared, and Dickens always spoke in the most affectionate terms of Perry's successor, John Black, under whom he served.

There has been much confusion between the two Tavistock Houses, and it has been repeatedly stated that Dickens lived in the same house as Perry, or in "a moiety" of it. We believe that the mistake is now for the first time corrected.

Dickens was of a restless and nomadic nature, seldom satisfied to remain long in one locality, and the nine years of his tenancy of Tavistock House was a much longer time than that spent without interruption in any other house except Gadshill. Chance or choice seems to have attracted him to the north-west quarter of London. As a child he stayed with his parents in Norfolk Street (now Cleveland Street), near the Middlesex Hospital, and when they moved to London it was to Bayham Street, Camden.

Then his mother put up her brass plate and attempted to run a school in Gower Street North, at "Miss Dickens's Establishment," Little College Street, Camden Town, and Johnson Street, Somers Town, next received them, and at one time another Charles lived with his father in the Polygon and in Bentinck Street, Marylebone. He went to a day school in Mornington Place, Hampstead Road. After his marriage he lived in Doughty Street for two years, returning to the north-west, to Devonshire Terrace at the top of Marylebone High Street. When he went to Lausanne to write *Dombey and Son* he sublet this house, and, returning before the subtenancy expired, he took a house in 1847 in Chester Terrace, Regent's Park. On finally leaving Devonshire Terrace he went for a time to Osnaugh Terrace, and then, in 1851, to Tavistock House. Here he remained till 1860, but after he took the house at Gadshill he spent much of his time in the country. After 1860 he had bachelor quarters at various places in London, one of which, at 5 Hanover Terrace, Regent's Park, should be included in our list. Besides these twelve addresses he had others in other parts of London and if the London County Council were to affix plaques to all his dwellings it would cost it a considerable sum.

Frank Stone, who occupied first Tavistock House and the Russell House was in A.R.A., the father of Marius Stone, R.A. and a great friend of Dickens. The latter, in a letter

Charles Dickens in 1859. After the portrait by W. L. With R.A. in the Victoria and Albert Museum, South Kensington. It was partly painted at Tavistock House. (Reproduced by permission of the Secretary and Director of the Museum.)

## TAVISTOCK HOUSE IN THE TIME OF CHARLES DICKENS

FIG 3—Tavistock Place North, showing Russell House (left), Bedford House (centre) and Tavistock House (right) with the entrance gate.

FIG 4—Garden in front of Tavistock, Bedford and Russell House (1900) showing the backs of the houses in Woburn Buildings.

FIG 5—Rear view of Tavistock House. Charles Dickens's mulberry tree is seen on the left. The mulberry tree is still in existence.

FIG 6—The back room on the first floor of Tavistock House in which Dickens gave his theatrical entertainments.

to his brother-in-law Austin, writes about his plan of turning Stone's painting-room into a drawing-room.<sup>2</sup> According to Mr. Kutton, Stone temporarily occupied Dickens's late dwelling in Devonshire Terrace, while Dickens was making alterations in Tavistock House.

The great Danish writer Hans Christian Andersen was the guest of Dickens, and has thus described the house:

In Tavistock Square stands Tavistock House. This and the strip of garden in front of it are shut out from the thoroughfare by an iron railing. A large garden with a grass plot and high trees stretches behind the house and gives it a comfortable look in the midst of this coal and gas steaming London. In the passage from street to garden hung pictures and engravings. Here stood a marble bust of Dickens so like him so youthful and handsome, and over a bedroom door and a dining room door were inserted the bas-reliefs of Night and Day by Thorvaldsen. On the first floor was a rich library with a fireplace and a writing table looking out

on the garden, and here it was that in winter Dickens and his friends acted plays to the satisfaction of all parties. The kitchen was underground, and at the top of the house were the bedrooms. I had a snug room looking out on the garden, and over the tree-tops I saw the London towers and spires appear and disappear as the weather cleared or thickened.

In his difficulties in trying to find room for the audiences of these performances, Dickens was advised to consult Mr. Cooke of "Astley's," then the most celebrated of circusmen. In *Forster's Life* there is an amusing letter from Dickens which, as it alludes to the drive and gates, may fitly be quoted here:

One of the finest things I have ever seen in my life of that kind was the arrival of my friend Mr. Cooke one morning this week (18th October 1853) in an open phaeton drawn by two white ponies with black spots all over them (evidently stencilled) who came in at the gate with a little jolt and a

rattle exactly as they come into the ring when they draw anything and went round and round the centre bed of the front court apparently looking for the clown. A multi-side of boys who felt them to be no common ponies rushed up in a breath less as they twined themselves like ivy about the railings—and were only deterred from storming the enclosure by the glare of the Inimitable's eye. Some of these boys had evidently followed from Actley's.

After Dickens gave up the house in 1860 it was occupied by more or less distinguished, or at least notorious, people. It is said that it was at one time used as a Jewish college or school. Then it was the dwelling of a lady whom the medical profession has good cause to remember. This was the singer Miss Georgina Welldon, whose actions at law and whose ability in conducting her own cases made a good deal of stir in the late seventies and eighties. The great French musician Gounod lived some months with the Welltons at Tavistock House and gave singing lessons in the drawing-room. Here he composed the music of *The Maid of Athens*, which he presented to Miss Welldon. At some time or other Eliza Cook, a minor poetess now almost forgotten, lived here. She was the authoress of "The Old Arm Chair" and other sentimental and popular poems.

William Collins, R.A., whose pictures were very popular and often engraved in the last century, lived for a short time in Tavistock Square, and there, in 1824, his son William Wilkie Collins the novelist, was born. As well known, he became a close friend and collaborator of Dickens and was a frequent visitor at Tavistock House during the latter's tenancy of it, when it was the meeting place of many distinguished people. The numerous visits of Dickens's tenancy formed the most brilliant period of his career. He was in the prime of life and in the fullest enjoyment of his great gifts. He came to be known to

act drop for this was painted by Clarkson Stanfield, R.A., in two days, and afterwards framed and sold at the Gadehill sale for a thousand guineas.

Buildings in which Carlyle lodged in 1831

The accompanying photographs show that the three houses were very pleasantly situated, shut off from the street by railings and giving a looking across the drive and shrubbery on to an extensive garden or field, and having at the back each its private garden which joined the large garden at the back of the north-western side of Tavistock Place. Tavistock and Bedford Houses were pulled down in 1800, and Russell House in 1901. The photographs which have been received from the Bedford Office, show Fig 3, a view of the entrance gates and the houses from the south west, and Fig 4 the field or garden across the road extending to the backs of the houses in Woburn Buildings, in No 6 of which Thomas Carlyle lodged for two months in 1831 when he was vainly trying to find a publisher on satisfactory terms for *Sartor Resartus* (Fig 7). Of it he wrote:

It is a very beautiful sitting room an inner bedroom above (and John sleeps with George) for which we are to pay 25s weekly. Quiet and airy and among known people.

From the back windows of this lodging Carlyle looked upon Tavistock House, in which in after years he was to be a frequent guest. The houses in Woburn Building which is but a court, are small and do not outwardly offer much prospect of immensity. When Mrs. Carlyle arrived to share the lodgings they were found to contain bugs, and the couple migrated to Ampton Street. In Fig 5 is shown the back of Tavistock House and "Charles Dickens's mill-berry tree", in Fig 6 the back room on the first floor of the house where Dickens gave his theatrical entertainment. These views no doubt represent the houses and gardens much as they were at the time Dickens first took Tavistock House although in the half century which had elapsed when the photographs were taken the shrubs and trees must have grown or been replaced.

I am much indebted to Mr. C. Fitzroy Doll, F.R.I.B.A., the architect and surveyor to the estate, who has very kindly had copies made from plans which he took when the three houses were demolished, and who had the plan (Fig 8) specially drawn to show the relation between Tavistock House and the new building of the British Medical Association. Another plan (not reproduced) of the ground floor of all three houses shows that the second Tavistock House was entirely an addition to the old house, not in lining the western wing of the latter, while the eastern wing formed part of Russell House. Fig 9

FIG 8—The hatched area shows the ground covered by the new building superimposed on the plan (in outline) of the old Bedford and Tavistock Houses.

the *Medical House*, *Hard Time*, *Little Dorrit*, *A Tale of Two Cities*, and *Great Expectations*. But the works were not enough for his restless energy. Beginning with the children's extracts on Twelfth Night, 1854, with the help of Mark Lemon and others, the smallest theatre in the world became celebrated and at every performance it was crowded with the leaders of literary and artistic London. The children of Dickens and of Mark Lemon seem to have displayed in natural drama powers and the song of Miss Wilkie's introduced (by desire) into Fielding's burlesque of *Tom Thum* so affected Thackeray that he rolled off his sea in a burst of laughter. *The Tighthouses* by Wilkie Collins was the first of the adult plays to be given. The

FIG 9

shows the first floor of Tavistock House in plan, including the theatre. In Fig 8 it will be seen that the end of the southern wing of the Association's new building covers part of the front portion of the house, including the staircase and a part of the theatre.

# THE BRITISH MEDICAL ASSOCIATION: ITS HOMES IN LONDON AND ITS SPREAD THROUGHOUT THE EMPIRE.

## THE OLD HOUSES OF THE ASSOCIATION (1871 TO 1925).

THE new house of the British Medical Association, graciously opened by the King last Monday, is the fifth it has occupied since, in 1871, it established its headquarters in London. The reason for these changes was not restlessness or inconstancy, but steady growth.

The purpose of the Association has not changed in the ninety-three years of its existence though the means it uses to attain its purpose have developed and expanded. There can be no doubt that Charles Hastings and the provincial physicians and surgeons who gathered round him at Worcester in 1832 would have been in full sympathy with the aims and objects of the British Medical Association to-day.

For a period there was a risk that the Association might determine to remain provincial. Had that policy prevailed it could not have attained the position it holds to-day of the great all-embracing medical institution carrying its organization directly or indirectly, but for the most part directly, into every part of the British Empire.

The fortunes of the British Medical Association have been very closely interwoven with those of its journal. In 1844 the Provincial Medical and Surgical Association, as it was then called, took over the *Provincial Medical and Surgical Journal*, which had been established four years earlier by two members of the Association. In 1856, by a unanimous

vote, the names of the Association and of the journal were changed to the British Medical Association and the British Medical Journal respectively.

Though the Association had many strong supporters who believed in its future, and though the results were very encouraging in some respects (and in particular in the interest it was arousing in social questions having a medical aspect), its growth during the third quarter of the nineteenth century was slow, and its position was far from satisfactory from the financial point of view. In 1871 the members numbered 4,403, the

Plymouth) that the management of the Association was in an unsatisfactory state owing chiefly to defective organization and supervision, and recommended that a business man should be appointed secretary, that his office should be in London, that he should collect subscriptions, manage the Journal, and obtain advertisements for it, be responsible for all the preliminary arrangements for the Annual Meeting, and act as clerk to the Council and committees and at general business meetings. These recommendations were accepted, and Mr. Francis Fowke, then house governor and secretary of the General Hospital, Birmingham, was selected for the post. The Association at that time was particularly strong in Birmingham, and its policy was in large measure influenced by a few active members resident there. It required some faith and courage to give up an appointment which if not offering promise of distinction in the future, was capable of expansion and was at least a certainty. But Fowke was imbued with a very real respect for the profession of his father, who had been a well-known surgeon in Wolverhampton, and was fortunately possessed of some private means.

He found the business of the Association and the management of its Journal conducted in two rooms over a shop in Great Queen Street, a small thoroughfare running eastward out of Drury Lane. Hart, who was in practice as an ophthalmic surgeon, edited the Journal from his consulting room, first in Queen Anne Street and afterwards in Wimpole Street. The Metropolitan Counties Branch was at branches then went, large and active, so that Fowke came at once into a friendly atmosphere, and the honorary secretary of the Branch, the late Dr. Alexander Henry, became Assistant Editor. Henry did most of his work in his own small house in the North of London, paying short visits on one or two days in each week to the manager and the printer.

Mr. Fowke brought to the duties of his new office force and tenacity of purpose, and quickly introduced strict business methods into the management of the Association's affairs. With this combination of a Journal conducted with enterprise and constant attention to the needs of professional readers, and of efficient business management the finances of the Association were soon placed on a satisfactory

FIG 1—Offices in Great Queen Street. X shows one of the two rooms occupied by the Association from 1871 to 1878. The additional accommodation taken in 1874 was in the next house the ground floor window of which is seen to bear the name of the British Medical Journal.

total income of the Association was £5,261, and the balance of income over expenditure was £38.

The BRITISH MEDICAL JOURNAL had at that time been edited for several years by Mr. Ernest Hart, who had devoted his remarkable energy and abilities to its conduct with so much success that its circulation had risen to over 7,000 copies weekly. The unsatisfactory position of the finances of the Association was, therefore, all the more disappointing.

### The Establishment of a Central Office in London

In 1871 the Committee of Council of which Mr. W. D. Hubbard of York was chairman, Dr. R. W. Falconer of Bath being treasurer, reported to the Annual Meeting (at

FIG 2—The house 1st Strand occupied by the Association from 1878 to 1885.

basis, and in 1874, when Mr George Southam of Manchester was Chairman of Council and Dr Paleoner still Treasurer, increasing business required, and the financial position justified, the taking of larger premises next door, at a rental of £30 a year. A photograph here reproduced (Fig 1) shows the offices in Great Queen Street at this time. Mr T Richards, whose name appears on the front of the shop, printed the JOURNAL from 1853 to 1878.

#### *The Association's First House in London (1878-1886)*

In that year the Association decided to undertake the printing of its JOURNAL, premises suitable for the purpose and to the then income of the Association were leased at 151, Strand. The Chairman of the Council when this first move was made was Dr Alfred Carpenter of Clowdon, and the Treasurer Mr W D Husband of York, upon whom and on Mr Powke the responsibility rested. The upper part of the new house (Fig 2) was occupied by the printing department, but the Committee of Council had a room for its meetings capable of seating thirty to forty persons, and a small room, stolen from a landing by the erection of a glazed wooden screen, was continued for the use on publishing days of the Assistant Editor, who was soon joined, as Sub-editor, by Mr Alban Doan, F R C S, who happily still lives and is engaged on the work of classifying and cataloguing the collection of instruments in the Royal College of Surgeons of England.

#### *The Second House (1886-1907)*

The membership of the Association the circulation of its JOURNAL and the receipts from advertisements all now began to show rapid expansion, and each year a substantial balance of income over expenditure, varying from £1 500 to £3 500, was shown on the year's working. In 1886 an opportunity occurred of acquiring the lease of the house 429 Strand formerly occupied by an insurance company. A sum of £4 500 was given for the lease and a little over £5 000 was expended on furniture and on the necessary alterations of the building. In 1888 the Association was able to purchase for the sum of £3 200 the lease of the two adjoining houses—Nos 2 and 3 Agar Street while in 1895 it acquired for £750 the lease of Nos 4 and 5 Agar Street. The aspect and extent of the offices occupied by the Association from 1888 to 1907 are indicated in the photograph (Fig 3) here reproduced. In 1894 the Association acquired in £4 640 the freehold of two small houses in a court immediately behind the front building and ultimately by an exchange with the neighbouring leaseholders obtained an L-shaped site upon which the building indicated was erected. Eventually the Association required the freehold of the houses in the Strand and Agar Street, the total amount expended in acquiring the

site and the buildings on it and putting them in order was £85,000.

#### *The Third House (1908-1925)*

The improvement of the accommodation provided in the several houses became an urgent matter in 1904. Various circumstances contributed to bring this about. The reorganization of the Association in 1902, leading to the election of a series of standing committees and the appointment of a Medical Secretary—who took up the full duties of his office in 1903—placed a great strain upon the resources of the old buildings, such provision as was possible was made for the committees and the Medical Secretary and his staff, but it had to be recognized that it was altogether inadequate for the proper conduct of the work. The Library had outgrown its accommodation, and the room in which it was arranged, though finely proportioned and not ill adapted for a reading room, was so completely unsuitable for the meetings of the Council, of conferences, or of large committees, that it was found desirable to accept the hospitality of the Metropolitan Asylums Board, which placed its spacious board room at the disposal of the Council for the quarterly and other meetings. Altogether the premises were found too small and it was realized that some change had become imperative. At first it was thought that it might be possible to

obtain the needed accommodation by remodelling the house in the Strand and rebuilding those in Agar Street, and in its own. The matter was very thoroughly investigated by the Premises and Library Committee appointed by the Council, under the chairmanship of Mr Andrew Clark, with the assistance of statements and estimates prepared by the General Secretary (Mr Elliston) the financial aspects of the questions involved were very fully considered. After several alternative schemes for partial rebuilding, the Council accepted the recommendation of the Committee that the wisest, and in the end the most prudent and economical course, would be to demolish the whole of the houses on the Strand and Agar Street site, and to erect on it a new building specially designed to meet the requirements of the business of the Association.

Preparations of the plans were thrown open to limited competition and on the advice of Mr William Henman, F R I B A, the task was eventually entrusted to Mr Percy Adams, F R I B A, who was instructed to plan the ground floor and basement so as to be suitable for letting for business premises, the Association reserving for its own use the five floors above the ground floor. The work of demolition was commenced at Easter, 1907. The old house was razed to the ground, and for nineteen months, during the rebuilding, the work of the Association was carried on in temporary premises in Catherine Street, Strand. Possession

FIG 4—The building erected by the Association on the site at the corner of Agar Street and the Strand (429 Strand) and first occupied at the end of 1907.

business premises, the Association reserving for its own use the five floors above the ground floor. The work of demolition was commenced at Easter, 1907. The old house was razed to the ground, and for nineteen months, during the rebuilding, the work of the Association was carried on in temporary premises in Catherine Street, Strand. Possession

was obtained of the new and enlarged premises in November, 1908, but the work of arranging the Library in the fine room provided for it was not completed until some months later. The General Office was established on the first floor, the Medical Secretary's on the second floor, and the Editorial Office on the fourth floor. The printing department was on the top story (fifth floor). The lofty Library gave an opportunity for a mezzanine between the first and second floors. This was used as an extension of the General Office, and the Medical Secretary's department eventually overflowed into the third floor. In this estimate of the space occupied by the Medical Secretary's department is included committee rooms. As the Association has twelve standing committees meeting in London, and as it is frequently necessary to appoint subcommittees or special committees, the strain upon the accommodation of the Medical Depart-

ment became increasingly great. This was one consideration which led to the search for a new site, another was that the house in the Strand provided no hall for large meetings such as a Representative Meeting, should one be called in London, nor for the conferences of representatives of Local Medical and Panel Committees, of which one at least is held every year, nor for large conferences between the Association and other bodies. Accordingly, the Council some years ago began to make inquiries, and after long search eventually found the site off Tavistock Square upon which there already existed a building, designed by Sir Edwin Lutyens, R.A., well adapted for the purposes of the Association, and including a large hall seating 500 people. The site had the further advantage of providing space for the erection of additional buildings should these become necessary in the future.

## THE AUSTRALIAN BRANCHES AND THEIR HOMES

[Dr R. H. Todd, Honorary Secretary of the Australian Federal Committee, has been good enough to write for us the following account of the Australian Branches and their homes, and of the Federal organization in Australia.]

AUSTRALIA has six Branches of the British Medical Association one in each State of the Commonwealth. They are the New South Wales, the Queensland, the South Australian, the Tasmanian, the Victorian, and the Western Australian Branches. They are co-ordinated in their activities by the Federal Committee of the British Medical Association in Australia and have a medical journal in common—namely, the *Medical Journal of Australia*. The Australian Medical Congress (British Medical Association) is constituted under the Federal Committee to hold sessions every year, every second year, or every third year as may from time to time be determined. The session is arranged for and undertaken by one or other of the several Branches in Australia or by the New Zealand Branch.

From the Australian Branches are the proud possessors of homes of their own, where they have their libraries and offices and hold their meetings, and the other two have their regular meeting places. The Branches are all vigorous institutions, alive to their responsibilities in promoting the medical and allied sciences, in maintaining the honour and interests of the medical profession and in carrying out the other objects of the British Medical Association in their own portions of the Empire. In all the public relations of the medical profession each Branch within its own State is recognized by the Government and the people as the organized body of the profession in the State and is competent to speak for the profession and in Commonwealth matters, the Federal Committee is looked to to act and speak for the whole profession in Australia.

The first three Branches to be formed were all recognized as Branches by the parent Association under its rules in the same year—namely, 1880. They were the Victorian, the New South Wales, and the South Australian Branches,

known respectively for some years after their formation as the Melbourne and Victorian Branch, the Sydney and New South Wales Branch, and the Adelaide and South Australian Branch. At that time the unit of the Association was the individual member, and not, as now, the Division or Division-Branch. There were in all the three Colonies in which the Branches were formed members of the Association who, for one reason or another, held aloof from the Branch. By the year 1902, however, when the Constitution was altered to provide that every member should be a member of the Branch in the area where he resided, not many members were affected by the alteration.

### THE VICTORIAN BRANCH

The first Branch to be established in Australia was the Victorian and the following facts connected with its origin have been supplied by Dr A. L. Kenny. Early in the year 1879 Dr Louis Henry returned to Melbourne from Europe with letters from the President of the British Medical Association empowering him to communicate with the members of the medical profession in the Australian Colonies with a view to the formation of Branches of the Association. The first provisional committee meeting was held at the house of Dr James Edward Nield, 165 Collins Street, Melbourne, on Thursday, September 11th, 1879. There were present Drs J. F. Neild, L. Henry, W. H. Cutts, J. Graham, M. Gillbee, Drs J. Jamieson, A. Morrison, McMillan, Mr J. Rudall and Dr Browning, all of whom are now deceased. On September 25th, 1879, the first general meeting of the Branch was attended by thirty members and a Council was elected as follows: President, Mr Gillbee, Vice-President, Dr W. H. Cutts, Honorary Treasurer, Dr James Graham, Honorary Secretary, Dr Louis Henry, Drs Neild, McMillan, Jamieson, Browning and Morrison, and Mr Rudall. At its first meeting this Council at once put itself in communication with the medical profession in the other Colonies with a view to the formation of Branches of the Association in New South Wales, South Australia, Queensland, Tasmania, and New Zealand. The result was very gratifying so far as the first two of these Colonies were concerned. By the end of the year 1879 the Victorian Branch numbered sixty-two members.

FIG. 1—The House of the Victorian Branch

now deceased. On September 25th, 1879, the first general meeting of the Branch was attended by thirty members and a Council was elected as follows: President, Mr Gillbee, Vice-President, Dr W. H. Cutts, Honorary Treasurer, Dr James Graham, Honorary Secretary, Dr Louis Henry, Drs Neild, McMillan, Jamieson, Browning and Morrison, and Mr Rudall. At its first meeting this Council at once put itself in communication with the medical profession in the other Colonies with a view to the formation of Branches of the Association in New South Wales, South Australia, Queensland, Tasmania, and New Zealand. The result was very gratifying so far as the first two of these Colonies were concerned. By the end of the year 1879 the Victorian Branch numbered sixty-two members.

The first Annual Meeting was held on August 6th, 1820, when the President, in his retiring address, disavowed any feeling of rivalry with the Medical Society of Victoria, members of which had furnished the bulk of the members of the Branch. Eighty-five members were on the roll at the second Annual Meeting on July 15th, 1881. It was pointed out that, without in any way hindering the progress or superseding the purposes of the older society (the Medical Society of Victoria), the Branch would take up subjects which, while strictly of a medical nature, had a more immediate relation to the general interest than those which were commonly discussed in medical societies, and, moreover, being in alliance with the Branches of the Association in the other Colonies, would be able to co-operate with them in the discussion of those broader questions with which purely local associations have less concern. The first Medical Society in Victoria was called the Port Phillip Medical Association. It came into existence in May, 1846, and was dissolved in 1857. The Victorian Medical Association was formed on May 7th, 1852, and the Medical-Chirurgical Society of Victoria on June 6th, 1854. These two bodies were amalgamated on June 18th, 1855, under the name of the Victorian Medical Society. This name was changed in the following year to the Medical Society of Victoria, and by it the society is known at the present day. The Victorian Branch of the British Medical Association and the Medical Society of Victoria, on January 4th, 1907, blended their constitutions in such a way that, to all intents and purposes, they became one body, membership of one implying membership of the other, and their councils and office-bearers being identical. Under this dual organization the Branch has the benefit of a grant of land, at the corner of Albert and Brunswick Streets, Melbourne, made to the Medical Society of Victoria in 1877, for the erection of a building for scientific purposes. A one-storied brick building was erected on the land, and the Medical Society of Victoria met there in its own "Medical Society Hall" for the first time on January 5th, 1878, when it celebrated its twenty-third annual meeting.

After the amalgamation of the two institutions, this building served as library, meeting-hall, and offices for the Victorian Branch of the Association until the present year, when it was demolished, and a handsome three-storied, well equipped modern concrete building has been constructed in its place. It contains on its ground floor a meeting hall capable of seating 350 persons, the library, 61 ft by 30 ft, is above the meeting-hall. A reading and writing room and council chamber and offices are also provided. On the ground floor is a large foyer, in which is placed the bronze memorial in memory of the members of the medical profession in Victoria who fell in the great war. On the third floor is a suite of rooms for the caretaker. The formal opening ceremony of the new home of the Victorian Branch took place on May 20th, 1925, reported in our issue of July 4th. The membership of the Victorian Branch is now approximately 1,200.

#### THE NEW SOUTH WALES BRANCH

The New South Wales Branch was recognized by the parent Association in the year 1880 at a time when there was no other medical society existing in the Colony. For several years previously the Medical Section of the Royal Society had served the purpose of the profession for the promotion of medical and allied sciences. In the first year

of its existence the New South Wales Branch had forty-two financial members. The numbers increased from year to year, and the activities of those members who had previously constituted the Medical Section of the Royal Society were transferred to the Branch. The membership of the Branch is now approximately 1,450. It is the largest Branch of the Association outside the United Kingdom. Of the original members the following still take an interest in its affairs: Dr. A. J. Brady, Dr. W. E. Warren, Sir Charles McKellar, Dr. T. H. Frasca, and Dr. William Clusholm.

For the first thirty years the meetings of the Association were held at the Royal Society's hall in Elizabeth Street, Sydney, and the Council for many years met in the library of the Editor of the *Australian Medical Gazette*, then the journal of the Branch, at 121, Bithurst Street, Sydney. In 1910 the Branch decided to have a building of its own. Land was purchased with a frontage of 64 ft to Elizabeth Street and a depth of 80 ft, and on it was erected the building of six stories which is known as the British Medical Association Building (30-34, Elizabeth Street, Sydney). The Branch went into occupation of its new home in March, 1911. The premises were so constructed that the first floor comprised a meeting-hall and library, together with reading rooms and offices for the Branch; the other floors were offices and business premises, which could be leased to suitable tenants. The purpose of the Branch in so constructing the building was that it should not only be a habitation for the Branch, but, in course of time, a source of revenue to enable it the better to carry out the objects of the Association in New South Wales. The names of Dr. W. H. Crago, now for thirty-six years the Honorary Treasurer of the Branch, and of Dr. G. H. Abbott, President for the year 1910-11 (the first graduate of an Australian university to fill that office), will always be associated with this building. It had its origin in their inspiration and foresight, and its successful completion was due to their enterprise. The management of the building has from its commencement been in the hands of Dr. Crago.

#### THE QUEENSLAND BRANCH

In Queensland it was not until 1894 that success followed efforts made from time to time for the formation of a Branch of the British Medical Association. As in most of the Colonies, attempts had for many years been made to organize the profession by the formation of medical societies. The first society of which anything is known was the Queensland Medical Association, which was founded in 1871. It had eleven members and lasted for nine months. In 1882 the Medical Society of Queensland came into existence. Its activities also were short-lived. It was, however, revived in 1886, and became an energetic and vigorous institution holding regular meetings for scientific purposes for many years. The funds of the old Queensland Medical Association of 1871, which were in the hands of trustees and amounted to £11 11s 3d, were transferred to the Medical Society of Queensland and were utilized by it for the purchase of books which, in course of time, became the nucleus of the present library of the Queensland Branch of the Association.

The Queensland Branch was brought into existence in 1894 on the initiative of Dr. I. Sandford Jellison, who was prompted to take steps for the purpose by Dr. Fletcher Little of London, whose acquaintance he had made when visiting England a few years before. The rules of the

British Medical Association at that time required that twenty-five members of the Association should requisition the Council for the formation of a Branch. As there were only three members of the Association available in Queensland at the time, some organization work was needed to augment their numbers. This was undertaken and resulted in a meeting being convened, the necessary requisition was duly made by twenty-five members, and the Queensland Branch was recognized by the Council in 1894. The inaugural meeting of the Branch took the form of a convocation at which His Excellency the Governor of Queensland, Sir Henry White Norman, G C B, and other distinguished visitors were present. In 1899 most of the members of the Medical Society of Queensland were also members of the British Medical Association, and a fusion of the society with the Queensland Branch of the Association was brought about mainly by the enterprise of Dr A B Brockway, who was for many years the honorary secretary of the Branch.

The Branch at that time numbered 108 members. It soon began to grow too big and to be too active to be without a fixed abode, especially as it had a library which required housing. Being merely a collection of individuals, the Branch was not competent to own land, but the difficulty of procuring a home was overcome by arranging for a number of members to become incorporated as the Queensland Medical Land Investment Company, Limited. This company then purchased the premises which are now known as the British Medical Association Building, Adelaide Street, Brisbane. This building consists of three stories, the lower two of which

FIG 3—The House of the Queensland Branch

a company, called the B M A Hall Company, Limited, composed of members of the Branch, was formed, and a building, which previously belonged to the Y W C A, was purchased in 1913, situated on the west side of Hindmarsh Square, having a frontage of 40 ft to the square and a depth of 100 ft, and a rear frontage to Hyde Street. The building, which was erected in 1902, is constructed throughout of red brick with grey cement facings. It consists of a basement occupying the whole area and of two floors. On the upper floor are five rooms leased to tenants. The ground floor consists of a large meeting-hall and three rooms, one of which is let to a tenant. The other rooms are the offices and library of the Branch. The hall measures 40½ ft by 30½ ft. It is furnished with blackwood chairs having an extended right arm rest for writing purposes, and handsome blackwood bookcases along the walls. At the entrance of the hall is a large ante-room and at the rear is a gallery and two small sitting-rooms.

In 1913 an appeal had arrived from London for help in erecting memorials in England to the memory of the late Lord Lister, which suggested the desirability of making a local memorial and naming the hall of the new British Medical Association building the "Lister Hall." The new hall was opened on June 28th, 1914, when, at the invitation of the President of the Branch (Dr B Poulton), Sir Harry Allen, the Dean of the Faculty of Medicine of the University of Melbourne, formally dedicated the hall to the memory of Lord Lister on behalf of the members of the Branch, and, at the same time, unveiled a portrait in oils of Lord Lister which had been presented to the Branch by Dr H S Newland. Sir Harry Allen then delivered an address on Lord Lister and his work.

The membership of the South Australian Branch is now approximately 340.

#### THE WESTERN AUSTRALIAN BRANCH

The next Branch to be formed was the Western Australian Branch, it was founded in August, 1898, and was duly recognized as a Branch of the Association in 1899. In that year it had 47 members, ten years later the number had risen to 98. In 1919 the number was 136, it is now 180.

#### THE TASMANIAN BRANCH

The last of the Australian Branches to be formed was the Tasmanian Branch, which was formally recognized by the Council in 1911. It has its headquarters in Hobart, and its regular meetings have always been held at the Royal

FIG 4—The House of the South Australian Branch

#### THE SOUTH AUSTRALIAN BRANCH

The South Australian Branch was formally recognized by the Council of the British Medical Association in 1880 at a time when there were a large number of medical men in Adelaide, especially those associated with Adelaide University, who were keenly interested in the progress of medical science. During the early years the meetings of the Branch were held first in the board room, and afterwards in the out-patient waiting-room, of the Adelaide Hospital. Later the University generously provided accommodation for the monthly and the annual meetings. In 1911, on the initiative of Dr W T Hayward, C M G, a movement was started to require a home for the Branch. As the result of his efforts and those of Dr H S Newland C B E, D S O, the then honorary secretary of the Branch,

Society's House in Macquarie Street, Hobart, which the members of the Branch regard as their home. Prior to the formation of the Branch, the members of the medical profession in Tasmania belonged to the Medical Section of the Royal Society of Tasmania, which was established in 1897 with the object of allowing members of the Royal Society who devoted their attention to particular branches of medical science fuller opportunities and facilities of

meeting and working together with fewer formal restrictions than were necessary at the general monthly meetings of the society, and also to guard the interests of the medical profession in Tasmania. The pioner of this Medical Section was Sir James Wilson Agnew, the President, Dr R S Bright, the Vice Presidents, Dr G H Butler and Dr L L Crowther, the Honorary Treasurer, Dr A H Clark, and the Honorary Secretary, Dr Gregory Spiatt. Dr Gregory Spiatt's name has been closely associated with the Branch since its inception, and he was its first President. He is the director of the Australasian Medical Publishing Company, Limited, representing the Tasmanian Branch and one of the Representatives of the Branch in the Federal Committee. Tasmania being by far the smallest of the Australian States, the Branch has the smallest number of members—namely, 100, which, however, is two thirds of the total number of medical practitioners resident within its area.

#### THE FEDERAL COMMITTEE OF THE BRITISH MEDICAL ASSOCIATION IN AUSTRALIA

With the development of the several Branches in Australia and the growth of their activities, the necessity for their co-ordination became more apparent year by year. Under the constitution of the Association, they had no relation to one another except through the Council and the Representative Body of the Association. On the other hand, they had many interests in common which called for local consideration and community of action. Among their greatest needs was a common journal, but, greater still, was the necessity for a Representative Body of their own. Australia had recently become a Commonwealth in which all the States were federated. There was a strong wish that nothing should be done to weaken the ties with the parent Association. The most obvious and appropriate method of organization of the Branches as between themselves was, therefore, some form of federation. The main difficulty to be considered was the great distance separating the centres of activity of the several States. It was inappropriate also that there should be centralization of the profession in any one State. The principle, therefore, was evolved of having a small committee in which each of the Branches should be equally represented, to consider all questions of common necessity to the Branches, and to act for the Branches in all matters of common concern. The constitution for the Federal Committee of the British Medical Association in Australia was accordingly drafted. It was adopted by each of the Branches in turn in 1912-13. Each Branch elected two of its members to be members of the Committee, and the first meeting of the Committee was held in Melbourne on May 27th, 1912, when Dr W T Hayward, C M G, was appointed Chairman, Dr (now Sir) George A Syme Vice-Chairman, and Dr G H Abbott Honorary Secretary. Dr R H Todd as Assessor was associated with the Committee in its inaugural work. The constitution was approved by the Council of the British Medical Association by letter, dated May 8th, 1914. The Committee, in the ordinary course, meets regularly twice in each year, the meetings being alternately in Sydney and Melbourne. In 1920 a meeting was held in Brisbane during the course of the Australasian Medical Congress (eleventh session).

The first task undertaken by the Federal Committee was the institution of a common medical journal for the Australian Branches. Its action in this direction resulted in the establishment of the *Medical Journal of Australia* as a weekly publication, which made its first appearance on July 4th, 1914.

The value of the Federal Committee to the Branches in Australia and to the Association as a whole has been fully recognized, and advantage was taken of amendment of the Articles of Association at the Annual Representative Meeting in 1923 to provide for a Federal Council of the Branches in Australia as a body within the constitution of the British Medical Association.

Apart from the establishment of a common medical journal for the Branches, the most important develop-

mental work entrusted to the Federal Committee has probably been in connexion with the Australasian Medical Congress. This congress, from the time of its inception in 1886 in Adelaide, has been held at three year intervals in the several capital cities of Australia and New Zealand, without having any definite permanent constitution providing for the continuity of its existence. The fact that it is now controlled and regulated by the Federal Committee and recognized as a British Medical Association Congress gives it both stability and permanence.

Dr W I Hayward retired from the position of Chairman of the Committee in 1922. The present Chairman, Sir George Syme, held the position of President of the first session of the Australasian Medical Congress (British Medical Association) Melbourne, 1923. The present Vice-Chairman, Dr W N Robertson C B J, is now on a visit to England as the Representative of the Federal Committee to attend—the invitation of the Chairman of Council, Dr R A Bolam—the ceremony in connexion with the opening of the Association's New House in Tavistock Square, Bloomsbury.

#### MEDICAL JOURNALS IN AUSTRALIA

Medical journalism in Australia has a long history. It may be said to have commenced sixteen years after the arrival in 1788, of the first fleet under the command of Australia's first Governor, Captain Arthur Phillip, R N, when Dr T Jamison, one of the surgeons of the first fleet wrote for public information an article on small pox which was published in the *Sydney Gazette* on Sunday, October 14th, 1804. The history of medical journalism in Australia is related in an extremely interesting article by Dr J H L Cumpston, the present Director-General of Health for the Commonwealth published in the first issue of the *Medical Journal of Australia* (July 4th, 1914) at page 11. In it Dr Cumpston gives the following tabulated statement of the medical journals published in Australia—namely:

1	<i>Australian Medical Journal</i> N S W	1846-1847
2	<i>Australian Medical Journal</i> Victoria after wards <i>Intercolonial Medical Journal</i> after wards <i>Australian Medical Journal</i>	1855-1914
3	<i>Medical Record of Australia</i> Victoria Afterwards continued as <i>Melbourne Medical Record</i> Victoria	1861 1863 1875 1877
4	<i>Medical and Surgical Review</i> — Australasian Victorian	1863 1864 1873 1875
5	<i>Australian Medical Gazette</i> Victoria	1869 1871
6	<i>New South Wales Medical Gazette</i> N S W	1870 1875
7	<i>Australian Practitioner</i> N S W	1877 1878
8	<i>Australasian Medical Gazette</i> N S W	1881 1914
9	<i>Intercolonial Quarterly Journal of Medicine and Surgery</i> , Victoria	1894 1896
10	<i>Journal of the Sanitary Inspectors Association of Western Australia</i>	1908

Of the ten journals enumerated New South Wales produced four and Victoria five. It was not until 1914 that there was a common journal for all the Branches. That year saw the commencement of the *Medical Journal of Australia*, which is now in its twelfth year. As stated above, the establishment of a common journal was the first task of the Federal Committee of the British Medical Association in Australia. At the time the Committee took the matter in hand there were two medical journals. One was the *Australasian Medical Gazette*, which was owned and conducted by the New South Wales Branch and published in Sydney, and which was accepted by the other Branches (except the Victorian Branch) as their official organ, the other was the *Australian Medical Journal*, conducted by the Victorian Branch and published in Melbourne. The Committee was faced with the constitutional difficulty that, not being a corporate body, it could not itself own a journal. A company, therefore, was formed, called the Australasian Medical Publishing Company, Ltd., with a constitution providing that all the members of the company should be representatives of Branches duly nominated by

the several Branches for the purpose. The members elect the directors of the company in the usual way, and the directors conduct the journal—the *Medical Journal of Australia*. Before the company was formed the Victorian Branch and the New South Wales Branch had generously handed over their respective journals to the Committee with a view to the new common journal being a Federal journal free of competition.

The company was registered in 1913 at Sydney, the first chairman of directors being Dr W H Craig (New South Wales), who had so successfully managed the *Australasian Medical Gazette* for many years in association with the late Dr C I Rennie, its editor. The other directors were Dr W N Robertson (Queensland), Dr F S Hono (South Australia), Dr Gregory Spiott (Tasmania), Dr W Kent Hughes (Victoria), and Dr the Honourable A J H Saw MLC (Western Australia).

The directors decided that an editor and a manager should be appointed who would give their whole time to the services of the *Journal*. Applications for the position of Editor were invited in England and in Australia. The present distinguished editor, Dr H W Aitnt, was selected from the many candidates. He was then associated with the *BRITISH MEDICAL JOURNAL*, and was well known as an organizer and for his work in medical research. At very short notice he gave up his career in England and came with his family to make his home in Australia. Within a few weeks of his arrival he produced the first number of the *Journal*. Shortly afterwards the great war broke out, and all the consequent difficulties affecting journalism had to be contended with. Nevertheless, he succeeded in establishing a paper which has now for many years been recognized among the medical periodicals of the world. The *Journal* had for some years to be set up and printed by contract, but in 1921 so good was its progress that it was able to dispense with the services of contractors so far as the type setting and composing were concerned. Now it has its own printing house, with a complete and up to date equipment and plant, and is not only altogether independent of outside assistance, but is undertaking general printing on its own account, especially of scientific and technical publications. A full and interesting illustrated description of the printing house, which is situated at Glebe, Sydney, is given in the issue of the *Journal* of April 11th, 1925. A copy of the *Medical Journal of Australia* is supplied weekly to every member of the Association in Australia in virtue of his membership, in the same way as the *BRITISH MEDICAL JOURNAL* is supplied.

#### THE AUSTRALASIAN MEDICAL CONGRESS

The institution now known as the Australasian Medical Congress (British Medical Association) was established in the year 1886 under the title of "The Intercolonial Medical Congress," and, as such, organized scientific meetings in the several Colonies or States of Australia and in New Zealand

every third year until 1905, the sessions being held as follows: 1886, Adelaide, 1889, Melbourne, 1892, Sydney, 1896, Dunedin, 1899, Brisbane, 1902, Hobart, 1905, Adelaide. After the federation of the Australian States as a Commonwealth the name of the congress was altered to the Australasian Medical Congress, and sessions were held under the new title as follows: 1908, Melbourne, 1911, Sydney, 1914, Auckland and 1920, Brisbane. At the meeting held in the year 1920, a referendum of the members of the congress was taken on the following question:

Are you in favour of the abolition of the Australasian Medical Congress as at present constituted in order that opportunity may be given of establishing congresses of the Australian Branches of the British Medical Association?

The voting on the question being in the affirmative, the following resolution was passed unanimously:

That the executive of the congress be empowered to wind up the affairs of the eleventh session of the Australasian Medical Congress and hand over to the Federal Committee of the British Medical Association surplus funds (if any) after the expenses of the congress have been met such funds to be passed on for the use of the future congresses of the British Medical Association.

The Federal Committee, at its subsequent meeting in February, 1921, resolved to establish British Medical Association Medical Congresses and to invite the co-operation of the New Zealand Branch. In another resolution it was determined that the objects of the congress should conform generally, *mutatis mutandis*, to those of the Annual Scientific Meeting of the British Medical Association. The first session of the congress under the new auspices was held in Melbourne in November, 1923, the President being Sir George Sime, FRCS, chairman of the Federal Committee. The congress was an unqualified success and, as could be judged from the reports published in the *BRITISH MEDICAL JOURNAL* at the time, set a high standard for future sessions.

The late Sir William Macrae accepted the invitation of the executive to attend this first session, and his distinguished presence as the ambassador of the Association was greatly appreciated by all the members as being further evidence of the feeling of kinship existing between the parent Association and its Overseas Branches.

The second session is being arranged by the New Zealand Branch and will be held at Dunedin in February, 1927.

In regard to membership of congress, whereas, under the previous constitution, every intending member had to apply to the executive on a form provided for the purpose and to be elected, under the present constitution every member of any Branch of the British Medical Association in Australia or of the New Zealand Branch is entitled to be a member without election, and every other member of the profession is entitled to apply for election.

## NEW ZEALAND.

The New Zealand Branch of the British Medical Association was established in 1896, when 104 members were enrolled. Its headquarters were at Christchurch, and the first permanent honorary secretary, Dr C Graham Campbell, held office from 1897 to 1902. By 1907 the membership had trebled and it was resolved to form Divisions within the Branch. In 1915 the number of members was 591 and in 1925 it had risen to 765. The Branch has fourteen Divisions: the Auckland Division has the largest number of members (170), the next in magnitude is the Wellington Division (117 members), the next Canterbury (99), and then Otago with 88. In March, 1924, it was decided to form a medical agency in connexion with the Branch office, to deal with the transfer of practices, the supply of locumtenents and the general safeguarding of the interests of the members of the Branch.

The Branch holds an annual meeting and at that held

in Auckland last year the President, Mr Currie Robertson, surgeon to the Auckland Hospital, said in the course of his address that in New Zealand many doctors had to carry on their practice entirely isolated in sparsely populated districts. Normally the New Zealand doctor worked alone, only occasionally, chiefly in the cities, did partnerships exist. In these circumstances the Divisions of the Branch form a talking point for the scattered workers, and though the membership of some of the Divisions is small they are of great value in affording opportunities for medical men to come together for discussion and to make or renew acquaintance.

As mentioned above, the next session of the Australasian Medical Congress is to be held at Dunedin, New Zealand, in February 1927. The *New Zealand Medical Journal*, the organ of the Branch, is published every two months, and 120 numbers have now appeared.

## THE BRITISH MEDICAL ASSOCIATION IN SOUTH AFRICA.

We are indebted to Dr. D. Campbell Watt of Pietermaritzburg, President of the South African Committee of the British Medical Association, for the following notes on the history and present position and prospects of the Association in South Africa.

In 1888, at a meeting of the South African Medical Association held at Cape Town, it was resolved that the local division of the South African Medical Association should merge itself in the British Medical Association and become a Branch thereof. This resolution was duly carried into effect, and the Branch was called the Western Province Branch (Cape of Good Hope).

Five years later the Eastern Province Division of the South African Medical Association also became a Branch of the British Medical Association. Shortly afterwards the Griqualand West Branch was formed at Kimberley, and in 1896 the Natal Branch followed suit. The Transvaal Branch was next added to the number, while the Border Branch was formed in 1906 as an offshoot from the Eastern Province Branch. The Transvaal Branch by a process of fission later on became the Witwatersrand Branch and the Pretoria Branch and in 1913 the Natal Branch was split into the Natal Coastal and the Natal Inland Branches.

In 1912 the Rhodesian Branch was formed, and the Orange Free State and Basutoland Branch came into being in 1913, at the time of writing a new Branch is being formed in Port Elizabeth and district.

The South African Branches, therefore, are now eleven in number, and in most cases they have been formed from antecedent societies.

## THE SOUTH AFRICAN COMMITTEE

Although the various Branches of the Association in the different Colonies and States exercised a salutary influence within their own spheres, especially on the legislative bodies in matters of public health and other legislation, in addition to the ordinary activities common to medical societies, yet it was felt that it was essential that there should be some combined body representing the entire Association in South Africa, able and willing to voice the views of the profession as a whole.

In 1906 the Western Province Branch therefore moved in the matter, and in 1909 the Central Council approved of the scheme submitted by the Branches for the formation of a South African Committee, subject to certain amendments, and it delegated many of its powers over the South African Branches to the Committee.

The Branches set to work, and by 1912 the Regulations of the South African Committee had been adopted and approved by the Council of the Association and the first office bearers appointed, the late Sir Kendal Friels, C.B., being its first President, Dr. Matthew L. Hewitt Vice-President, and Dr. D. Campbell Watt Honorary Secretary and Treasurer. The Branches represented at the inauguration of the South African Committee were the Western Province Branch, the Eastern Province Branch, the Griqualand West Branch, the Border Branch, all of Cape Colony, the Transvaal Branch, and the Natal Branch.

The existence of the South African Committee has been fully justified. Many subjects of interest to South African practitioners have been taken up, and some success has attended its efforts.

## MEDICAL CONGRESSES

Shortly after the formation of the Committee it was decided that in the future the medical congresses should be held annually in the auspices of the British Medical Association, and in 1913 regulations were adopted governing the congress and appointing the South African Committee of the Congress as a permanent organizing committee of each congress.

The 1924 Annual Congress has been held in Pietermaritzburg, as recorded in our last issue, p. 79.

## MEDICO POLITICAL ACTIVITIES

The Committee was consulted by the Union Minister of Defence regarding the regulations dealing with the Medical Department of the Citizen Defence Force, and many of the alterations proposed by it were adopted. The necessity of appointing school medical officers was urged upon the Government with success. The establishment of a separate Department of Public Health, with a Minister, was advocated, and when the present Public Health Act was before Parliament the then President of the South African Committee gave evidence before the Select Committee, and prior to the bill being drafted he was appointed a delegate to a public health conference dealing with the proposed legislation, and his efforts proved highly successful in moulding the bill on the lines advocated by the South African Committee.

A consolidating Medical, Dental, and Pharmacy Bill has been before Parliament several times, and last year a vigorous attempt was made by Christian Scientists, chiropractors, and other cult practitioners to obtain State recognition under the bill. Evidence was given by them on the one side, and by the President of the South African Committee and other representative medical practitioners on the other side, before a Select Committee. The bill is again before Parliament this session, and as it stands contains no recognition of these cults. The profession is hopeful that the bill will go through as drafted in this regard, although there is a surprisingly large element of sympathy for these cults both in and out of Parliament.

Evidence was given by the President of the Committee before the Government Hospitals Commission, when he advocated the proposals which had from time to time been adopted at various congresses and by the South African Committee. Many of the Branches also sent witnesses to give evidence before that Commission. The Western Province Branch Parliamentary Committee has on several occasions held a watching brief for the Association, and done much to inform members of Parliament with regard to measures affecting the profession.

It was deemed advisable by the Committee to draw up a *Guide to Medical Ethics*, and the guide has received commendation from the medical press, and proved itself useful.

A voluntary benevolent fund has been established by the Committee, and arrangements made with several insurance companies for the issue of medical defence policies to practitioners.

## THE FUTURE

The Association in South Africa had the pleasure of the presence of Dr. J. A. Macdonald, a Vice President of the Association and lately Chairman of Council, at the Congress held in Durban in 1920, and he paid a visit to most of the local Branch headquarters during his stay in the country. His visit was productive of much good.

The career of the British Medical Association in South Africa has not gone unchallenged. Several attempts have been made to establish a South African Association, the latest and greatest being within recent years, but on that occasion, by a small majority of the members, it was resolved to adhere to the British Medical Association, although a large proportion of the entire profession was in favour of a local association, affiliated with the British Medical Association. As a sequel to this position the Council of the Association most generously offered substantial financial aid in the appointment of an Organizing Medical Secretary for South Africa, but as a corresponding sum could not at the time be guaranteed by the Branches the Council has kept the offer open for a year.

Meanwhile the South African Committee and the Branches are making special efforts to increase the membership of the Association by the issue of appeals to non-members and the appointment of Branch organizing secretaries. At the present time the Association embraces about one-half of the practitioners in South Africa.

## CANADA.

The organization of the British Medical Association was extended to Canada a good many years ago. The first Branch—Halifax, in Nova Scotia—was recognized in 1867, in 1891 the Montreal Branch and the Manitoba and North-West of Canada Branch were recognized, and in 1894 the British Columbia Branch. Afterwards Branches were recognized in Toronto, Saskatchewan, and New Brunswick.

Two highly successful Annual Meetings of the Association have been held in Canada—the first in Montreal in 1897 under the presidency of Dr. (afterwards Sir) Thomas Roddick, and the second in 1906 in Toronto, when Dr. R. A. Reeve was President. At the time of the meeting in Montreal the profession was much concerned to obtain from the Canadian Parliament an Act to remove certain legislative anomalies which hindered the free practice of medicine throughout the Dominion and also full reciprocity with this country. Dr. Roddick, as the leader of the Canadian profession in this matter, he visited every province to explain his scheme, and from his place in the Canadian Parliament urged its advantages year after year. The Canadian Medical Act was passed in 1902, but the Provinces which had hitherto had control, each in its own area, were slow to relinquish their privileges, and it was not until 1912 that it was possible to constitute the Medical Council of Canada, of which Dr. Roddick was elected the first President. It is not, we think, too much to claim that the two Annual Meetings of the British Medical Association held in Canada did much to assist the reformers there and to convince others of the possibility and of the advantages of the unification of the profession in the Dominion. Both meetings were attended by a large number of members from this country, and this alone was sufficient to convince our Canadian brethren of the keen interest the home members took in their difficulties—difficulties which had been overcome here—and in their welfare generally. After the Canadian Medical Council was established and legal unification was in existence, there still remained the task of bringing about the voluntary organization of the profession in Canada. The Branches of the Association in the Dominion languished and the Canadian Medical Association formed in 1867, when the Provinces were federated and a Dominion Parliament established, did not flourish.

After the war, in which the Canadian Army and its medical officers took so fine a part, the position of the Canadian Medical Association was taken in hand and it became apparent that that association, extended to the

whole Dominion, was in the opinion of the profession there better adapted to its needs than any reorganization of Branches of the British Medical Association could be. Discussions took place between the Canadian Medical Association and the British Medical Association which ended in the elaboration of a scheme for the affiliation of the Canadian and British Medical Associations. The Council at home was able to induce Sir Jenner Veall and the Medical Secretary (Dr. Cox) to accept a cordial invitation to visit Canada in the spring of 1924, and then the details of affiliation were finally adjusted. That scheme is now in force. Arrangements were made for intercommunication and the exchange of information, and members of the Canadian Medical Association were given the right to attend the Annual Meeting of the British Medical Association in this country and its Sections, to make use of the British Medical Association house and library, and to command the help of the central staff of the Association there. The Canadian Medical Association in addition to giving similar facilities to members of the British Medical Association undertook to nominate persons to act at Annual Meetings of the British Medical Association in the British Isles.

These plans are now working. Information is already being exchanged and more and more members of the Canadian Medical Association are resorting to the headquarters staff in London for help and advice on various matters. The British Medical Association has been able to arrange for some of its prominent members to visit Canada and to take part in the annual meetings of the Canadian Medical Association. Quite recently, as we mentioned a few weeks ago, the President of the British Medical Association Mr. Basil Hall, visited Montreal, Toronto, Winnipeg, Ottawa and other parts of Canada as a representative of the British Medical Association. He received a very warm welcome everywhere, and the address he delivered to the Academy of Medicine in Toronto is published in this issue. Mr. H. W. Carson, by invitation, gave addresses on surgery at the Annual Meeting of the Canadian Medical Association at Regina in June last. Further evidence of the success of the new plans is afforded by the fact that the largest and most representative delegation of Canadian medical men which has ever attended a meeting of the Association in this country has been present this week at the opening of the New Building, and will take part in the Annual Meeting at Bath.

## WEST INDIES

The British Medical Association has been active in the West Indian Islands for nearly half a century. The first Branch, that in Jamaica, was founded in 1877, and the number of its members has increased to 64. The second Branch to be recognized was in British Guiana (1883), it has steadily maintained its membership, and publishes

reports of its work in a volume entitled the *British Guiana Medical Annual*. The Bermuda Branch was founded in 1886, and the Barbados in 1889. In the following year the Leeward Islands Branch was recognized. In 1892 the Trinidad and Tobago Branch was founded. Grenada Branch followed in 1916, and the St. Lucia Branch in 1923.

## INDIAN AND OTHER ASIATIC BRANCHES.

The first Branch of the British Medical Association founded in India, or in the East, was the Bengal Branch organized in 1863 by the late Surgeon-Major Norman Chevers. The Branch was at first well supported and had a numerous membership, both of service men and of private practitioners—European and Indian. In 1867 Dr. Mohendra Lal Sarkar, a leading Indian physician read a paper advocating homoeopathy, to which he had become a convert. The discussion caused by this paper practically broke up the Branch, though it lingered on for a few more years. In 1879 an attempt was made to reconstitute the Branch, but the profession in Calcutta preferred to start an independent society—the Calcutta Medical Society. This body had a

successful career of some fifteen years. It published a monthly fasciculus of proceedings. For over half a century Calcutta, the former capital of India, has been unrepresented in the Association.

In 1882 the late Surgeon-Major C. W. Shirley Deakin, an I.M.S. officer of great ability and energy, started the North-West Provinces and Oudh Branch. Deakin enlisted a large membership, nearly two hundred, chiefly officers of the A.M.D. and I.M.S. but with a fair sprinkling of European private practitioners. Its meetings were held at Allahabad, and Deakin, as editor, published a monthly periodical, at first under the name of *Transactions*, which in 1885 became the *Indian Medical Journal*. This Branch came to grief in

1885 over a paper read by the late Lieut-Colonel (then Surgeon) Andrew Duncan, entitled "The insurmountable tendencies of State sanitation," the language of which was both intemperate and insubordinate, though the views of the causation of cholera advanced by Duncan were opposed to the theories then in official favour, strongly supported by Surgeon General J. M. Cunningham, the then head of the I.M.S., they have been proved by time to be correct. Duncan published Duncan's paper in the *Indian Medical Journal*, and supported it in a strongly worded leader. Both Derkin and Duncan suffered. Derkin went on far longer, and on his return was relegated to military duty in the Punjab. With his departure from Allahabad the North-West Provinces Branch died out. On his return from furlough he resuscitated it as the Punjab Branch. Most of the members of the defunct North West Provinces Branch joined the new one, which lasted for some four years. Derkin died of enteric fever at Jhulam on November 17th, 1889. After his death the Branch came to an end, as also did the *Indian Medical Journal*. Both the North-West Provinces and the Punjab Branches, though named after the provinces which were then headquarters, had members all over India.

The third Indian Branch, in date, was the South Indian and Madras Branch, founded on October 4th, 1883, and recognized in 1884. This is not only the oldest existing, but has been the most successful Indian Branch. It has now lasted over forty years, and in membership stands second only to Bombay. It publishes its *Transactions* monthly. In fairly rapid succession followed the Bombay and the (second) Punjab Branch in 1889, the Burma Branch in 1891, and the Deccan Branch in 1894. The last died out, or was in a state of suspended animation for some years, but has been resuscitated as the Hyderabad Branch. Three other Branches have since been added—Assam in 1908, Baluchistan in 1910, and Northern Bengal in 1922.

In April last the Association mustered eight Branches and over a thousand members in India, as follows:

	Recognized	Members
South Indian and Madras	1884	143
Bombay	1889	193
Punjab	1889	88
Burma	1891	63
Hyderabad (Deccan)	1894	30
Assam	1908	55
Baluchistan	1910	13
Northern Bengal	1922	13
I.M.S. officers not attached to any Branch		288
Other members outside area of any Branch		140
Total		1,026

There are four other Branches in Asia, outside India: the Ceylon Branch, recognized in 1887, with 206 members, Hong Kong and China, 1891, 169 members, Malaya, 1894, 202 members, and Mesopotamia, 1921, 45 members. Though far beyond the geographical boundaries of India, the last might almost be considered an Indian Branch, its membership consisting chiefly of R.A.M.C. and I.M.S. officers of the Indian Army. The Hong Kong and China Branch is increasingly active in spite of its insular position and local transport difficulties. Two meetings were held in 1923, but in 1924 it was decided to hold monthly meetings. At the invitation of the Branch to the Chinese Medical Missionary Association, a very successful joint medical conference was held in Hong Kong in January, 1925. The Ceylon Branch has published a journal for the last twenty-two years. The annual meeting of the Malaya Branch are now held alternately in the Federated Malay States and the Straits Settlements. Dr. J. W. Schriiff, honorary secretary of the Branch, acted as secretary and treasurer of the fifth congress of the Far Eastern Association of Tropical Medicine at Singapore in September, 1923. More than 300 medical practitioners attended from fifteen different countries, and nearly sixty papers were submitted dealing with tropical diseases and the opium evil. The active co-operation of the Branch and the energetic work of Dr. Schriiff contributed very largely to the value and success of the congress.

The Association has always used its influence to press the just claims of the great public medical services, each of which has, in turn, had cause to be grateful for the support given to it by the full weight of the profession in Britain, exercised through the Association. On at least three occasions during the last half century has the I.M.S. been helped by it. The first was over the "unemployed pay" question, in the early eighties, when the service had been over-recruited, till its strength was quite out of proportion to the number of appointments available, and a large number of juniors were drawing what was called "unemployed pay" while on general duty. Some of them had little work to do, as superintendents, assistants to senior officers in regiments, others, on choicest duty or similar work, were really working harder than the men drawing full pay. The second time was when the pay of nearly all ranks was considerably increased, in 1902. And the third was when both pay and pensions were again raised, after the war. On such questions also as command pay, specialist pay, and study leave, help to press the claims of the service has been readily given.

medical service, including nursing, in the Highlands and Islands of Scotland and otherwise providing and improving the means for the prevention, treatment and alleviation of illness and suffering therein." The Board of Health, which is the counterpart in Scotland, as far as regards powers and duties, of the Ministry of Health in England, administers this Act and as a result of its operation conditions of practice in the Highlands have been very greatly improved. Grants are made to individual practitioners, and in some instances a minimum income is guaranteed in return for which practitioners undertake to visit dependents of insured persons and persons of the crofter class at a standard scale of charges. The adjustment of the scale and of the grants is no easy matter, and finality has not been reached, but a fairly satisfactory working arrangement has been come to. A Highlands and Islands Committee of the Scottish Committee has been set up, and through it practitioners serving under the Act can express their views collectively. The Board of Health now recognizes that committee as representing the practitioners and regularly consults with it on all matters pertaining to the conditions of service.

Even apart from the Highlands, Scottish health legislation and administration differ considerably from English. The Public Health Acts are different, as is also the Education Act. The Insurance Act is the same in essentials, but is administered separately from England and differs in detail of administration. In all of these various spheres the Scottish Committee and its subcommittees find scope for activity and useful work for the profession. Testimony to the value of that work was made by the Secretary for Scotland in a recent speech, when he said that he believed the relationship between the Association and the Board of Health in Scotland had been not only of a friendly but essentially of a useful nature.

In a more restricted but still important sphere good organizing work has been done—namely, in connexion with contract practice in colliery areas. The Colliery and Public Works Surgeons' Committee, which, though not a committee of the Association, is organically connected with the Scottish Committee, succeeded some years ago in establishing a national rate of payment in substitution for the various district agreements formerly in force, and has successfully maintained the rights of the profession to reasonable remuneration.

The scientific side of the Association's work is likewise well maintained. The clinical demonstrations arranged by the Edinburgh and the Glasgow and West of Scotland Branches, and the clinical and scientific meetings of the Fife Branch and the South-Eastern Counties Division and other Divisions, are specially noteworthy.

The successful Annual Meeting in Glasgow in 1922 had a markedly stimulating effect, and the Annual Meeting which is projected for Edinburgh in 1927, when the centenary of Lister will be celebrated, is already being looked forward to with pleasurable anticipation.

The new Scottish House of the Association, the auspicious opening of which in Edinburgh was recently reported in

our columns,<sup>1</sup> marks a new era in the development of the Association in Scotland. Providing as it does imple office and other recommendation for the immediate purposes of the Association, it promises also to fulfil the function of a medical centre for Edinburgh and for Scotland. That the Scottish Committee may be trusted to promote and uphold the high ideals of the Association is evidenced by the speech of the chairman, Dr C. C. Douglas at the opening ceremony. Prefacing his remarks with a note of the extension of the membership in Scotland, he went on to say: "Such extension is all to the good. We must expand. It is true that the doctor is essentially a born individualist, he, like the soldier, feels that in the last resort it is his own hand, his own brain, may I add perhaps his own wits, by which he stands or falls. But just as the soldier, brave though he may be, is as nothing without the organization of the modern army behind him, so in our day no man can be at his best living apart from our great organization of the British Medical Association. And we have thus to offer him, that if he will join us, to his fine ideal of individual enterprise and energy there shall be added that other great ideal of devotion to a good cause, the maintenance of the 'honour and respectability' of the profession to which he belongs. It is an interesting thing to note how a great ideal attracts to itself the best men, and we see this in the history of our Association. From Sir Charles Hastings, our founder, who I like to think was a graduate of Edinburgh University in 1818, on to Sir Victor Horsley himself, there were always fine men at the head of its affairs. We should never, in a gathering like this, forget to think of Horsley, the father of this modern, self-governing, democratic Association of ours. Since his time we have always had good men at our head, and even now I am struck with the quality of the men whom one meets in the Council. There are men—I may not name them as some of them are here—who for intelligence, for sagacity, for devotion to our proper interests, might find an honourable place on the directorate of any of the great industrial enterprises. They say that we are a trade union. To that I reply that, while we may act as much like a trade union as may be done by the members of a learned profession, we work under a maxim—the fine old Roman law, *Salus populi suprema lex*—the which, were it acted upon by the great trade unions of this country, many of the evils under which we suffer would disappear. I say—and our records are all open to examination—that never in the history of the Association has anything ever been carried that is opposed to the general good of the community, and I feel certain that it never will. We have other functions. You may have noticed that we have above us the Scottish Meteorological Office of the Air Ministry. It appears to me that we ourselves act as the medical meteorological office—always on the look-out for storms, with this advantage, that we do something about these same storms when they do arise—a useful function not yet attempted by the other office."

## IRELAND

### THE IRISH FREE STATE

THE Dublin Branch of the British Medical Association was established in 1877, its area corresponded approximately with that now included in the Leinster Branch. In 1895 it consisted of 120 attached and 202 unattached members, making a total membership of 322. The majority of these members resided and practised in the city of Dublin and its adjoining townships. The Leinster Branch now includes the counties of Dublin, Kildare, King's, Longford, Louth, Meath, Queen's, West Meath, Wicklow, and Wexford, except a small portion adjoining County Wexford. The south-western portion of Wexford with County Kilkenny and the County, Carlow, although in the Province of Leinster are not included in the Leinster Branch, and form a portion of the

area included in the South-Eastern of Ireland Branch. The Dublin Branch during its existence was prominently identified with Irish medico-political questions, and its leading members took an active part in the promotion of public health legislation and in the improvement of the position of Poor Law medical officers in Ireland. The majority of the members of the Dublin Branch were engaged in private practice, as is the case to day. They became members of the Association in order that they might be in a position to help their colleagues who were less fortunately placed in the public services and to share in the scientific side of the Association, and especially to receive its JOURNAL. In 1905 the Leinster Branch had a membership of 329, which fell in 1915 to 164 as the result of the increased annual subscription and had times generally

for medical practitioners in Ireland rising out of the European war. To day the membership of the Leinster Branch stands at 252. It must be remembered that a very considerable number of the younger members of the Association, especially of the Leinster Branch, leave Ireland each year to practise in Great Britain, the Dominions, and Colonies. The East and South of Ireland Branch was recognized in 1893, and in 1895 it had 41 attached and 104 unattached members. This Branch, with the South-Eastern of Ireland Branch, included all the Munster area and the extreme southern portion of Leinster. The East and South of Ireland Branch is now known as the Munster Branch, and includes the counties of Clare, Cork, Kerry, Limerick, and the North Riding of Tipperary. The medical population in Munster is small and scattered, as the province is almost entirely agricultural. The Munster Branch in 1905 consisted of 99 members, but owing to cruises similar to those which operated in Leinster the number of members declined. It has since increased, and the Branch has at the present time a membership of 102, which is the highest since its formation. The South Eastern of Ireland Branch was also recognized in 1893. In 1895 it had 37 attached members and 24 unattached. In 1905 its membership was 65, in 1915 it was 45, and in 1925 it was also 45. The South Eastern of Ireland Branch includes in its area the counties of Carlow, Kilkenny, Tipperary (South Riding), Waterford, and the south western part of Wexford which it adjoins the County Waterford. The Connaught Branch includes the Province of Connaught, it was recognized in 1903. In 1915 it had 31 members, and in 1925 this had increased to 40. Thus there are in the Free State four complete Branches. The Irish Free State counties of Carlow, Donegal, and Monaghan are included in the Ulster Branch with the six counties under the Northern Parliament. The four entire Branches in the Free State consist of fourteen Divisions. Of these, there are six in the Leinster Branch, three in the Connaught Branch, three in the Munster Branch, and two in the South-Eastern of Ireland Branch. There is also in the Free State the Monaghan and Carrigrohilly Division, which belongs to the Ulster Branch. The County Donegal (Free State) members of the Association are attached to the Derry and County Fermanagh Divisions of the Ulster Branch.

Besides the Branches and the Divisions there is a Standing Committee—the Irish Committee. The President, Chairman of Representative Body, Chairman of Council, and Treasurer are members *ex officio* of this Committee. The additional *ex officio* members are the Secretary of each Irish Branch and the members of Council representing Irish Branches. In addition there is one member appointed by each Irish Branch, but, if the Secretary of the Branch is a member of the Council, two members appointed by each Branch. Any member specially appointed by the Leinster Branch or by the Ulster Branch must be a practitioner not resident in Dublin or Belfast. Three to eight members selected by the Irish Committee at its first meeting each year complete the full list of members of the Irish Committee. The Irish Committee considers all matters specially concerning Ireland. It has its own Medical Secretary (Dr. T. Hennessy) and its own Irish Offices (16, South Frederick Street, Dublin), where it attends to all Irish medical questions.

### THE ULSTER BRANCH

In 1877 a number of medical men met in Belfast and resolved to form a Branch of the British Medical Association. It was decided to call it the North of Ireland Branch. Dr. James Cuning was elected first president, and Dr. John Moore honorary secretary and treasurer. Three general meetings besides the annual meeting are held usually in Belfast, but occasionally in other towns, and the average attendance is about 35. The Branch has grown steadily, and at the annual meeting this year, with Professor McIlwaine as president, the honorary secretary, Mr. H. P. Mulholland, M.C., reported a membership of 440. The agenda contained a list of a score of members who showed patients and demonstrated specimens. The clinical side of the Belfast Medical School holds a position almost of the time, and recognizes with gratitude the ever ready help of the Association and Journals. The representatives of the Branch on the Council and central committees are diligent in attendance, despite the distance, and offer their contributions to the discussions of the business of the Association at the same time they take back to Northern Ireland much useful information. Many clinical papers of scientific interest have been published from time to time in the *Journal* and have served to ventilate the views and discoveries of medical practitioners in Ulster and of the teachers in the medical faculty of the Queen's University of Belfast.

In 1884 the Annual Meeting of the Association was held for the first time in Belfast, under the presidency of the late Dr. James Cuning, professor of medicine in the then Queen's College. This meeting, at which a large amount of professional work was done, served to widen the outlook of the medical men of the Province, and acted as a stimulus to the scientific work of the school. In 1901-2, when the constitution of the Association was being reorganized, and Dr. J. S. Darling (Lurgan) was president of the Branch, and Dr. W. Caldwell (Belfast) honorary secretary, one of the tasks that had to be undertaken was the adjustment of the boundaries of the Divisions. Some difficulties were encountered, but they were eventually overcome, and the arrangements then made have continued in force with a few minor alterations until the present time. The Ulster Branch is practically co-terminous with the geographical area of Northern Ireland, and is very active, especially in Belfast. The Association met again in Belfast in 1909. Sir William Whittham, M.D., was President, and over 1,500 members attended. The late Sir John Biers gave the address in Obstetrics, and much useful work was accomplished in the scientific sections. This meeting served again to bring the unity of the profession home to those in Ulster who did not attend the annual meetings in other towns, or indeed rarely the branch meetings, and acted as a stimulus to the scientific work of the school.

The Ulster Medical Society is an old local society, serving the clinical wants of Belfast itself, and many country Fellows are assiduous in attendance at its meetings, it is in a flourishing condition, and publishes annual *Transactions* of much clinical value. The society and the Branch are complementary to each other, the friendliest relations existing between them, most Belfast practitioners are members of both, and in any general question of moment a committee formed from the councils of both is appointed to voice the views of the profession.

Country Life

## THE NEW HEADQUARTERS OF THE BRITISH MEDICAL ASSOCIATION

### DESCRIPTION OF THE BUILDING

THE GREAT HALL FROM ONE OF THE AISLES

on its side Bloomsbury is a region rapidly coming into its own once more after many years of comparative neglect, and the direct route from Kingsway to King's Cross is one which will presently be of the first importance. It is towards the northern end of this route that the House stands.

The New Building had been completed up to a certain point when it was taken over by the Government during the war. It was acquired by the British Medical Association two years ago from the Disposals Board on advantageous terms, the lease from the trustees of the Duke of Bedford's estate is for 200 years. The outside had to be completed and a great deal of work was necessary to the interior before it could be fitted, under the direction of Sir Edwin Lutyens, R.A., to the purposes of the Association.

The building has as many qualities as the site. Its broad façades were drawn by Sir Edwin Lutyens in sober

and austere mood, they were originally designed to house a religious organization, which may have had something to do with it. The plan is of that delightful enclosing U-shape which is the principal charm of so many of our collegiate and other buildings in which a great many people live and work together. The open space of the U is, however, approached through a broad passage which separates the central Court of Honour from Tavistock Square.

and austere mood, they were originally designed to house a religious organization, which may have had something to do with it. The plan is of that delightful enclosing U-shape which is the principal charm of so many of our collegiate and other buildings in which a great many people live and work together. The open space of the U is, however, approached through a broad passage which separates the central Court of Honour from Tavistock Square.

#### THE MEMORIAL GATES

Entering through this roadway (flanked on each side by buildings which will one day yield place to extended wings of the new edifice), the first objects that strike the eye are the beautiful Memorial Gates opening into the Court of Honour, and beyond the Gates the façade of the main block with its stately windows. The Gates or Remembrance are of wrought iron, and their design is founded on the choicest examples of eighteenth century work. They are surmounted by a bronze shield bearing on either side a legend lettered in gold: in front "Memoria

and praise," behind "Faithful hath been your warfare." They have been made by the Birmingham Guild to the design of the architect leafwork and scroll form the main feature. The total width of the gate and railings is 60 feet, the height at the centre is 24 feet. They have been erected by the Association as a tribute to the 574 of its members who fell in the war and whose names are inscribed in the Boole of Honour.

[Country Life]

the main block, which are the most conspicuous feature of the building itself, naturally suggest the existence of some apartment of great consequence, and in accepting their evidence we shall not be disappointed. The Great Hall into which they admit an abundance of light is an

#### THE GREAT HALL

The lofty windows of

THE GREAT HALL

[Contd. 1 p.]

imposing room approximately a double cube one hundred and thirty feet long. The simplicity of the whole building is here very logically maintained. The roof above this hall is supported on semicircular ribs of light steel framing, which remains unadorned except at each end where one bay is surmounted by a painted vault moulded to the shape of the ribs behind it. Modern conditions demand that beauty should be continued directly out of the useful and inexpensive, and in his treatment of the roof and vault of the Great Hall Sir Edwin Lutyens has complied with this demand in an extremely skilful way. The inside of the roof itself together with the many subsidiary members of the framing that support it are painted a nocturnal green, if such a colour exists (which we doubt), and against this shadowy background the semicircular ribs appear in narrow ribs of gold. The whole is supported upon a row of Corinthian columns whose shafts appear as though turned out of some brilliant peacock blue marble. This remarkable effect appears, upon close inspection, to have been achieved by means of paint. At the north end of the hall is a door, and at the south a gallery, running from end to end at the lower level of the roof is an ambulatory connecting the third floors of the north and south wings of the building.

#### *Library and Common Room*

Centrally below the Great Hall there runs a vestibule which connects the Court of Honour entrance with that in Burton Street. Entering this vestibule from the courtyard, there will be found on the left the Library, panelled in fine Spanish mahogany turned from the old house of the Association. On the right is the Members' Common Room, a spacious apartment with long French windows overlooking the Court; its walls are finished in white and a delicate pearl grey—the lightest and most ethereal grey

imaginable. A narrow black slitting helps to punctuate the subtle gradations of the walls. Below the rooms are large basement offices, containing the staff dining room and additional printing machine rooms, beside storage accommodation for the library.

#### *Hastings Hall and Council Room*

The windows of the Common Room and Library are repeated in the façade of the north and south wings, but the apartments lighted by them are several feet below ground floor, and are approached by flights of stairs and passenger lifts placed at each end of the wing. There are in the north wing, the Hastings Hall, capable of seating one hundred and fifty persons, and in the south wing the huge Council Chamber. Both halls are similar in shape and design, the ceiling springing from the walls in an ample cove entrenched by the rich ceilings over the window openings. The colour scheme in each hall is a combination of white with a pale ochreous yellow. Artificial illumination is provided by means of inverted bowls resting on little gilt pedestals of very interesting design. The floor of the Council room rises in tiers, and on these tiers are rows of comfortable seats upholstered in green leather. The walls are lined with oak panelling bearing the names of past Presidents, Chairmen, Gold Medalists, Editors, and other dignitaries and officials of the Association.

#### *Court of Honour*

The building covers eighteen thousand square feet, and has a total floor space of fifty thousand square feet. On its north it is flanked by a modern utilitarian garage, on its south by the Council's garden, whose pleasing sweep all springs from the old foundations of Tavistock House, where Charles Dickens lived and worked. Within the main courtyard the corners of the quadrangle are paved with

ELEVATION OF GREAT HALL (INTERIOR).

flagstones in a graceful curve, and the roadway leading from the Memorial Gates to the archway under the Great Hall surrounds a large circular grass plot with a wide kerb of white stone. A harmony in red, white, green, and grey is the result, with the delicate black tracery of the Gates in the foreground.

We may close this brief description of the new building with a note on the way in which the interior of the two wings has been laid out to take the various departments among which the central work of the Association is distributed.

#### Departmental Accommodation

On the first floor of the north wing, over the Hastings Conference Hall, are the general offices concerned with the business of publishing, subscriptions, and advertisements, on the second floor is further accommodation for the Finance Department, with rooms for the staff of the

Medical Insurance Agency. On the third floor is the Editorial Department, with rooms for the Editor, Assistant Editor, Sub-editor, and clerical staff. Above this, on the fourth floor, is the printing office, with type-setting machines, compositors' cases, and rooms for proof-readers.

The first floor of the south wing, over the Council Chamber, contains several fine committee rooms, and houses also the Intelligence Officer and her staff. The two floors above are allocated to the Medical Department. On the second floor are the rooms of the Medical Secretary, Deputy Medical Secretary, and Assistant Medical Secretaries, and the third floor accommodates the four committee clerks, the staff in charge of the card index and files, and the remainder of the clerical staff of this department. The fourth floor, arranged as a residential flat, is leased to the Financial Secretary, accommodation is also provided in the building for a resident medical officer.

GROUND PLAN OF SITE OF THE ASSOCIATION'S NEW HOUSE

The building as it stands is indicated by stippled shading; the sites of the proposed future extensions, on each side of the roadway from Tavistock Square, are shaded in vertical lines.

# British Medical Journal.

SATURDAY, JULY 18TH, 1925

## THE OPENING OF THE NEW HOUSE

ANOTHER chapter in the history of the British Medical Association began last Monday when the King, its Patron, visited the new site and formally opened the House in Bloomsbury which it has required and equipped. The members of the Association are deeply sensible of the honour paid to them, and to the profession they stand for, by this visit of their King and Queen. The close interest taken by Their Majesties in the progress of medical science and art, and their unflinching sympathy with the work of our profession for the relief of sickness and suffering, are matters of common knowledge. But this Royal Opening of the new House is so signal a compliment to our organization, its aims, and its work, that we make bold to describe it as a landmark in medical history. Physicians throughout the ages, and surgeons in later times, have had acknowledgement of their worth from State and Crown, but for the great body of general practitioners, who bear the heat and burden of the day, there has hitherto been little recognition. The British Medical Association, however, represents the profession as a whole, and in honouring this society our Sovereign honours us all.

Ever since it was founded in 1832 the British Medical Association has aimed at the integration of medicine for the common good, and this ideal is expressed in the Address presented to Their Majesties in the name of the Association on July 13th. During the past ninety three years specialization has spread far and wide and the conflict of material interests has threatened it times to split our ranks, but under the wise guidance of men of broad outlook the Association has continued to promote the advance of medical and allied sciences, and has gone far towards achieving its ideal of professional unity within these Islands and throughout the Empire. That its membership, now approaching 30,000, is world wide has been shown this week by the presence in our midst of leading medical representatives from Canada, Australia, New Zealand, South Africa, and India, and from distant Colonies and Dependencies, all bearing messages of loyalty and goodwill to the parent body. Moreover, hundred societies at home and abroad have sent delegates to join with us in celebrating this notable event in our annals. The position held by the British Medical Association in the public and professional life of this country is indicated by the fact that the Minister of Health accompanied Their Majesties as Minister in attendance, and that among those who awaited the Royal visitors, standing beside the principal officers of the Association, were the President of the General Medical Council, the Presidents of the two English Royal Colleges, Lord Dawson who represents medicine

at Court and in the House of Lords, and the Chief Medical Officer of the Ministry of Health and the Board of Education.

It was most fitting that these outward signs of the solidarity of our profession in this country and throughout the British Empire should have included the dedication and opening, by the Archbishop of Canterbury, of the beautiful Memorial Gates set up by the Association as a tribute to the 574 of its number who fell in the great war. In the minds of all who enter the new House for work or study or pleasure, the gates they pass through will "wake remembrance of these valiant dead."

The brilliant success of the ceremonies on July 13th was the reward of infinite care and attention to detail. Nothing that foresight could provide for was overlooked, and the gracious message of congratulation from the King and Queen, received on the following morning and printed at page 145, will be endorsed by all whose good fortune it was to witness the day's proceedings. The letter from Buckingham Palace expressing Their Majesties' admiration for this splendid building, their pleasure in opening it, and their appreciation of the excellence of all the arrangements, is one of those kindly and discriminating acts that round off a high compliment.

## A PAGE OF HISTORY

THE account given elsewhere of the offices the Association has occupied since, in 1871, it established its headquarters in London is proof that the growth of its varied activities has been so rapid that the prudent anticipations of one generation have been found inadequate in the next. It has now a house amply providing for the administrative needs of to-day, and the control of a site which affords room for a great deal of expansion. The house now taken into use contains, in addition to offices for the three departments, a spacious Library, a members' conversation room, a fine Council Chamber, committee rooms, and a Hall capable of seating five hundred people, upon the design and decoration of which the architect, Sir Edwin Lutyens, has lavished his great powers.

Probably the most important decision the Association ever took was when in 1856, it resolved to take the name 'British Medical Association'. With its old name of 'Provincial Medical and Surgical Association' it could never have become the Empire wide institution it is. It had done a great deal of valuable work for the advancement of clinical medicine and the ancillary sciences, and also for the betterment of sanitary conditions, for the amendment of laws and regulations which in the new industrial era had become obsolete, and it had persistently sought for a reform of the Poor Law. This was work for the whole of Great Britain but without perhaps fully appreciating what it was about it had embarked on a still wider field. It had long been asking Parliament to establish a 'Medical Register' to which should be admitted only those who fulfilled certain conditions, the chief of which was that the applicant should produce evidence of having attained a certain standard of education by passing through a curriculum prescribed by the universities and medical colleges. This Register, during the transition period when the Dominions and Colonies were growing to nationhood, was Empire wide.

Later on the Association accomplished much for the public health and for social medicine generally, chiefly through the Parliamentary Bills Committee, which though it had a rather anomalous constitution was in effective body. But as the number of members grew the constitution of the Association itself got out of date. Its government was originally established on the representative principle by way of a large Council elected through the Branches, this Council met once a year and delegated its duties in the intervals to a Committee of Council. As the membership increased the constituents grew too big and a large proportion of members belonged to none. They were called 'unattached', they belonged to the Association in order to receive the *BRITISH MEDICAL JOURNAL* and to have the right to attend the Annual Meetings. In this way the organization came nearly to resemble that of a public company with an annual general business meeting open to every member, and a Council which, though not elected by the business meeting had functions very similar to those of a board of directors. This plan never worked well, and as the number of members grew it worked less well. The unattached members did not feel that they were responsible for the policy followed by the Association in medico-political matters and its influence with Parliament, with the Government, with the public, and with the profession itself, was thereby seriously impaired.

The main object of the alterations in the organization of the Association which were under discussion at the beginning of this century, and were embodied in the constitution which came into force in 1902, was to consolidate and extend the social and medico-political work the Association was doing and to establish its right to speak in the name of the whole profession. To attain the second purpose it was decided that every member of the Association should be a member of the Division within whose area he resided. In order that the work under the first head should be effectively done, a number of standing committees were set up, and a whole time Medical Secretary appointed to act as secretary of these committees, to prepare the business for them, and to carry out the instructions they might give. The work under this head very quickly increased, and the staff of the Medical Secretary's department had to be enlarged. There is now a Medical Secretary, a Deputy Medical Secretary, and two Assistant Medical Secretaries, besides a Secretary for Scotland and another for Ireland, with offices in Edinburgh and in Dublin respectively. At the present time there are fifteen standing committees concerned either with internal administration or with matters affecting the relation of the medical profession to public affairs. The standing committees work in consultation with the Council which meets seven times a year and is the executive of the Association. The Council reports its recommendations to the Representative Body, this body which contains representatives of all the Divisions both at home and overseas meets at least once a year and in it is vested the general control and direction of the policy and affairs of the Association. In this way the constitution of the Association has become strictly representative.

The attainment of this object was the second decision of supreme importance reached by the Association the first as has been said was that it should be an organization bounded in area only by the limits of the British Empire. In Australia it has six Branches one for each State they hold joint congresses periodically and are co-ordinated by a

Federal Committee, on which all the Branches are represented. In South Africa there are eleven Branches, and here is a committee (the South African) existence and joint congresses for scientific discussion are held. It is the great growth of the work of the Association in medico-political directions that has rendered imperative larger accommodation than was foreseen by those who were responsible for the erection of the house in the Strand which has just been vacated. The need was found for more committee rooms—the standing committees, of course, are empowered to appoint subcommittees, and sometimes the Council appoints special committees—and for larger rooms. The common room, originally provided for the use of members, was eaten up by the growth of the clerical staff and there was no large hall for meetings of the Representative Body, for conferences of representatives of Local Medical and Panel Committees, and for other largely attended conferences with other bodies—such, for example, as those that were held to discuss the policy the profession should follow with regard to voluntary hospitals. The new house in Tavistock Square provides for all these things, and the prudent course has been followed of acquiring the control of the sites at present occupied by the houses which lie between the building opened by the King last Monday and the main thoroughfare.

#### PRESIDENTIAL CHAIR GIFT FROM AUSTRALIA

At the Council meeting on January 18th last the Chairman stated that a letter had been received from Dr. R. H. Todd, Honorary Secretary of the Federal Committee of the British Medical Association in Australia, with regard to a proposal from the Australian Branches to present the parent Association with some gift for the New House, such as a chair, which should be made of Australian timber. On receipt of this letter a cablegram was sent to Australia saying that a President's Chair for the Great Hall would be most acceptable. The Federal Committee thereupon cabled £100, with a request that the chair be made in this country, and that the High

Commissioner for Australia, Sir Joseph Cook, and also Mr. Joseph Davis, formerly Director of Public Works in New South Wales, should be consulted with regard to material and emblems. Dr. Bolam added that the High Commissioner and Mr. Davis had very willingly responded and made suggestions. The Council authorized a letter

to be sent to Austria conveying thanks for this welcome gift. The Presidential Chair has been carved and upholstered according to a sketch furnished by Sir Edwin Lutyens, the architect of the building. It is constructed of the Austrian wood known technically as black beech, and upholstered in red leather. The back of the chair bears, in front the Austrian coat of arms, and behind, stamped in gold lettering on a leather panel, the following inscription, in accordance with a suggestion by the Austrian Federal Committee:

#### BRITISH MEDICAL ASSOCIATION

##### PRESIDENT'S CHAIR

Presented by the Branches of the British Medical Association in Austria

to

the Parent Association in England

in token of

friendship, loyalty and goodwill,

to celebrate the Entry of the Association into its New House,

Travistock Square, London,

July, 1925

"... the which, though light as air, are as strong as links of iron"

The quotation at the end of the inscription is taken from the famous speech of Edmund Burke in the House of Commons in 1775 on conciliation with America. At the reception in the Great Hall held on the evening of July 13th the chair was formally presented to the Association by Dr W. N. Robertson, C.B.E., as delegate from the Austrian Federal Committee, of which he is vice-chairman. The speeches at the presentation are reported in our account of Monday evening's ceremony (p. 146).

#### CONVENTION OF ENGLISH SPEAKING OPHTHALMOLOGICAL SOCIETIES

A CONVENTION of English speaking Ophthalmological Societies was held in London this week under the auspices of the Ophthalmological Society of the United Kingdom and its affiliated societies in the provinces, in Scotland, and in Ireland. A large and very representative number of members attended. On the eve of the opening of the convention some 700 names had been registered, the list included visitors from all parts of the Empire, from France, Holland, Switzerland, Austria, and China, and from the United States of America, which was represented by about 230 delegates, among whom were some of the best known in ophthalmic literature. On Monday evening, before the official opening of the convention, a reception was given by the President and Council of the Royal College of Surgeons of England. The guests, who included many ladies, were received by Sir John and Lady Bland Sutton. The whole of the museum of the College was thrown open, those sections bearing on ophthalmology, especially in the fine war collection, being particularly prominent. Members and their friends were entertained by a programme of music, and refreshments were provided in the library. The function, which was very well attended, provided a happy opportunity for introductions prior to the official opening of the convention. From mornings, three afternoons, and an evening were devoted to the scientific work of the convention, whose meetings were held in the University College buildings. During this time a heavy programme was gone through, which included two discussions, the Bowman Lecture by Sir John Parsons, and thirty-nine original papers, to which members from overseas contributed largely. The social aspect also of the meeting was well catered for: its items included a reception by the President of the convention, Mr. Tiercher Collins, a reception at the Royal Institution by its President and Council, a garden party given by Sir William and Lady Lister,

and excursions to institutions of ophthalmic interest in London, to Oxford, and to Cambridge. At University College an interesting and comprehensive museum had been prepared of drawings, instruments, and pathological and anatomical specimens, a feature of which was the number of sections illustrating much of the recent original work that has been done both in this country and in America. The official banquet which terminates the proceedings is being held in the Guildhall on Friday evening, July 17th, H.R.H. the Duke of Connaught is the guest of honour. One of the primary aims of the convention was the re-establishment of international congresses of ophthalmology on a pre-war footing. In taking the initiative in this the Ophthalmological Society of the United Kingdom is to be congratulated. The success and value of these meetings in the past, and the enthusiasm of the present convention, provide the strongest argument in favour of their continuance on the broadest possible basis.

#### SIR JOHN ROBERTSON MOH BIRMINGHAM

To celebrate the honours of knighthood recently conferred upon Sir John Robertson (M.O.H. Birmingham), he and Lady Robertson were entertained at dinner on July 16th by the Midland Branch of the Society of Medical Officers of Health. There was a large attendance, and the President, Dr. R. Wolsey Stools, who was in the chair read letters of congratulation and apologies for absence from many others, including the Minister of Health (Mr. Neville Chamberlain), Sir George Newman, Professor Kenwood, Dr. Bolam (who conveyed the compliments of the Council of the British Medical Association), Professor Bostock Hill, and Professor Hope. In proposing the health of Sir John and Lady Robertson, Dr. G. F. Buchan, president-elect of the Society of Medical Officers of Health, professed congratulations on behalf of the society. He recalled Sir John's long service to Birmingham, and the singular value of his association with the university. Dr. Buchan said that he had first come under the influence of Sir John Robertson's energy and enthusiasm sixteen years ago. Research was the keynote of his policy—research for its own sake—and its practical application, this should be made the slogan of every medical officer of health, so lifting his work above politics and contemporary outside influence. Sir John had always been a great worker, and certain changes in the sphere of public health would always be intimately associated with his name: housing in relation to health, a pure food supply, especially milk, the campaign against tuberculosis, which he might be said to have initiated in Birmingham, maternal mortality, cancer research. Dr. Buchan expressed his pleasure that Sir John had been recognized and honoured during his lifetime. He had established an ideal of public health administration, and, great as he was to-day, he would appear still greater to posterity. Councillor Miss Bartlett (chairman of the Birmingham Health Committee) made a short and happy speech, paying tribute to Sir John's helpfulness and personal attributes. The toast was received with acclamation and musical honours. Sir John Robertson, in replying, spoke feelingly of the honour done to him by those gathered together that evening. His knighthood, he said, was a recognition of the public health service and of the work of medical officers of health generally, and he would carry it in their name. Public health work was happy work, though results were not immediate and could only be secured by pegging away. He had been consistently lucky all his life in being country bred, and thus early acquiring a knowledge of nature, in his masters at school, in his father, who sent him to Edinburgh, where he gained an intimate knowledge of natural history. Fiddles and music also played their part in his education, but in spite of these distractions he qualified. He was fortunate in

becoming associated with a good general practice, and regarded such experience as of the greatest value to a medical officer of health. His first appointment was at St. Helens, where he was lucky in his health committee, whose members helped in every possible way. Again at Sheffield he was no less happy, and looking back on his service in Birmingham he had no regrets. He recalled the names of Sir William Cooke, Mr. John Nettlefold (of town planning fame), Sir Ernest Hiley, and Mr. Neville Chamberlain as among those who had been greatly helpful. He closed with words of deep appreciation of the honour done to him. Mr. J. Furner Jordan, President of the Birmingham Branch of the British Medical Association, who proposed the toast of the Society of Medical Officers of Health, said that the profession as a whole was proud of the distinction conferred on Sir John Robertson. He looked upon the medical officer of health as something of a superman, for to the knowledge of the ordinary doctor he added that specialized knowledge that made him what he was. Mr. Jordan referred to the great reduction in the general mortality rate, and expressed the hope that with the more complete instruction now insisted on or in contemplation by the General Medical Council and the Central Midwives Board the perinatal mortality rate would show an equal diminution. The problem of cancer could only be solved by Sir John's method of "pegging away." Dr. R. A. Lister, President of the Society of Medical Officers of Health, responding, expressed the appreciation of the society at the honour done to Sir John Robertson, and said that it reflected on the whole public health service. The society endeavoured to secure the best and most brilliant men for preventive medicine.

#### ACTION OF LIVER EXTRACTS IN HIGH TENSION

The Canadian Medical Association Journal for July contains two articles relative to the action of liver extracts upon arterial hypertension. An editorial in the same issue states: "One of the papers is purely an experimental laboratory study, the other might be termed an experimental clinical study. The authors of both were associated for a period and exchanged ideas although at the time working from different hypotheses. What the ultimate benefit will be is a problem for the future, but it is gratifying to note in members of the Canadian profession not only the investigating mind but the generous co-operation with fellow workers." The shorter paper, that by A. A. James and V. B. Lughton of the University of Western Ontario Medical School describes experimental work upon rabbits, using intravenous injections of liver extracts after injection of such pressor substances as epinephrine (1 ccm of a 1 in 10,000 solution). The exact method of preparing these extracts is not stated. The authors conclude that: (1) Extracts of liver used in experimental animals effectually reduce the hypertension induced by certain pressor substances. (2) These extracts will reduce normal blood pressure to a low level (about 5 mm Hg) where it is maintained over long periods of time. (3) Large doses reduce the blood pressure to its lowest level and death ensues. (4) Preliminary work suggests strongly that the active substance is not choline or histamine. The other paper, by W. J. McDonald of St. Catharines, Ontario, accounts the results he and others who helped him obtained by injecting a solution of liver extracts into the veins of persons suffering from "essential hypertension." These results are illustrated by charts, and curves of changes induced in the normal blood pressure of rabbits are also given. The exact method of preparing the extracts is not stated. Dr. McDonald began his work by investigating the effect of liver extracts from the liver of mice acid in the blood of those suffering from carcinoma, for it had previously been shown that in such

patients there is generally a definite increase in the acid content of the blood. Later he found in one of his carcinomatous patients that injections of liver extract reduced the blood pressure so that he determined to test these extracts in a series of patients with essential hypertension. Shortly afterwards a change was made in the method of obtaining the liver extracts and Mr. W. M. McDonald, a biochemist of Hamilton, Ontario, succeeded in recovering from the extract what appeared to be the active principle in two fractions which were termed chemicals "A" and "B." Thirty-three clinical cases were studied in all, and extracts of varying dosage were injected intravenously. The usual dose seems to have been 2 ccm up to 4 ccm every two or three days. In twenty-five patients no disagreeable symptoms whatever were caused, but in another eight patients reactions followed which in varying degree resembled protein shock. In these eight cases the two chemicals "A" and "B" were combined in one injection. The age of the patients ranged from 42 to 67 years (average 61), the average duration of hypertension was six years, the average systolic blood pressure before injection 204 mm Hg, afterwards it was 142, the average diastolic pressure before treatment was 114, and this fell on the average to 86 mm Hg. Dr. McDonald states that the exact chemical nature of the liver extracts has not been ascertained, but this is being investigated in the University of Toronto. Dr. McDonald presents his results "without conclusions or deductions."

#### INDUSTRIAL FATIGUE

The fifth annual report of the Industrial Fatigue Research Board, which was published last month chronicles the progress of investigations covering a wide field, and includes some short papers by members of the research staff. Among subjects of inquiry having particular medical interest we note that at the request of a departmental committee appointed by the Home Secretary to consider and report upon the statutory regulations governing the use of artificial humidity in cotton factories, the Board has undertaken an inquiry into the relative incidence of sickness upon weavers in wet and dry sheds. The investigation will be carried out under the supervision of a special committee, of which Dr. Myron Greenwood is chairman and Professor I. E. Collis a member. Another research committee, of which Mr. C. J. Bond is chairman and Dr. Greenwood, Hield, Pembrey, and Pirnau members, is investigating telegraphists' cramp, and a committee, of which Dr. Leonard Hill is chairman and a majority of the members medical men, is studying the physiology of ventilation. In the last named field extensive use is being made of Dr. Hill's kymograph, a new method of measuring oscillations in air temperature by means of a delicate thermopile, invented by Mr. J. J. Manley and Dr. Vernon, is noted. It is remarkable that an increase in the oscillations of air movement has been found to cause a distinct increase of the subjective sensations of freshness, and that a simple method of increasing these oscillations, depending on intermittency in the running of the ventilating fan, has been tried. These observations may prove of much practical importance. Miss E. M. Newbold contributes an excellent paper on the pitfalls waiting the interpreter of industrial sickness statistics. She repeats the old but frequently forgotten caution that correlation does not necessarily imply causation, and calls the following excellent instances of high correlation—between the secular course of expenditure on the navy and the consumption of bananas, between ability to speak Dutch and a low rate of mortality from cancer of the breast, and between the amount of calcium in one's bone and

the number of nephews and nieces and his Miss May Smith writes on the psychological factors of industrial efficiency "It is not uncommon," she remarks, "to be told by a girl that she has nothing much wrong except that she suffers from nerves. Some employers, however, are seriously perturbed about the loss of efficiency involved in the form not only of sick leave but of inadequate work and of irritability affecting fellow workers as well. People of robust type scornfully dismiss the problem with the magic word 'hysteria,' but a label is neither soothing nor practical when the alternatives of dismissing the worker or of enduring the 'nerves' are confronted." Mr. L. L. Limer contributes a very cautious note on methods of detecting liability to accidents. The report does not record any one arresting discovery but contains ample evidence of careful, routine work which is what is needed in this field.

#### BRITISH EMPIRE CANCER CAMPAIGN

The annual report of the Grand Council of the British Empire Cancer Campaign for the year ended May 31st, 1925, was presented at the meeting held at the House of Lords on Monday, July 13th. In his introduction the chairman, Viscount Cave, announced the receipt of subscriptions to the amount of just over £100,000. He pointed out that it has been the principal aim of the Grand Council to co-ordinate and encourage all deserving institutions and individuals engaged in cancer research work. Thanks to grants from this society, several laboratories which would otherwise have been restricted by lack of funds have been able to continue research work, and in some cases to open up new lines of investigation. Work is being carried out with radium and 2 rays under a committee appointed jointly with the Medical Research Council, £5,000 worth of radium was purchased in the early part of the year and put at the disposal of this joint committee. In addition a radon centre for the production of radium emanations was founded at the Middlesex Hospital and financed by the Campaign. The report contains a summary of the work of the various committees during the past year. The Scientific Advisory Committee meets each month to consider matters referred to it by the Preliminary Inquiry Committee and the Grand Council, together with various reports on investigations carried out at its instigation. The body of the report is taken up with statements from institutions in receipt of grants. The Cancer Research Department of the Middlesex Hospital has received £6,900, the Cancer Hospital Research Institute £5,000, the Medical Research Council (on behalf of the radon centre at Middlesex Hospital) £3,725, St. Bartholomew's Hospital £1,695, Christie Hospital, Manchester, £1,000, Tropical Disease Prevention Association £1,500, Cancer Research Laboratories of St. Mark's Hospital £600 and the Coombe Lying in Hospital, Dublin, £200. The statement submitted by the Middlesex Hospital refers to general pathological investigations, experimental researches, diagnostic serological methods, and radiological researches. The report from the Cancer Hospital Research Institute goes very fully into the experiments Dr. Leitch and his co-workers have been carrying out on the experimental production of cancer by carcinogenic substances, as reported by Dr. Knapp in our columns a fortnight ago. Reports are submitted also on researches in clinical and surgical pathology, immunity experiments, experiments in chemotherapy, and statistical inquiries. Promising work is reported from the cancer research laboratories at St. Mark's Hospital, where a detailed investigation has been begun into the relation of simple and malignant tumours of the large intestine. Among the inquiries that are being carried out by individuals to whom grants have been made may be mentioned those of Dr. Thomas Lumsden at the Lister Institute. He is at present investigating the effects

of antisera in cancer and sarcoma, and results already obtained *in vivo* suggest that important knowledge may be gained by these researches.

#### THE AUTOMOBILE ASSOCIATION AND THE OFF SIDE RULE

At the twentieth annual meeting of the Automobile Association on July 8th it was announced that the membership now exceeds a quarter of a million. The annual report dealt with the activities of the association, in its parliamentary, legal, touring, and engineering departments. A paragraph of the report of interest to members of the British Medical Association is headed "Road safety—off-side rule." It is stated that the committee, after full consideration, has unanimously decided to recommend all members of the Automobile Association to adopt the "off-side rule." At present there is no standard rule for deciding at cross- and side-roads which vehicle should proceed and which should give way to other traffic. The report continues "The underlying principle of the 'off-side rule' is that every user of the street is made responsible primarily for avoiding collisions with any vehicle or person on his *right hand*. Applying this principle to cross-roads, a driver would wait for, and pass behind, any vehicle approaching from his right, and when a driver cuts in from his near side the onus would be upon him (presumably the near-side driver) to explain his reasons for so doing should an accident occur. Briefly stated, the rule means 'Watch for, and, other things being equal, give way to, traffic approaching from the right.'" The wording of the paragraph is not, perhaps, as clear as it might be, but this proposal was made many years ago by a medical motorist, Dr. Charles Buttai, whose argument was published in the *BRITISH MEDICAL JOURNAL* of February 21st, 1925 (p. 380). Later on the matter was raised at a meeting of the Metropolitan Counties Branch Council by Mr. Bishop Hayman, and again the proposal was approved unanimously. At that meeting it was suggested that the metropolitan police should be approached for the purpose of disengaging the rule in connexion with traffic regulation. It was decided to postpone acting on this suggestion and to communicate with the Automobile Association and other motoring organizations. But a joint discussion between the Automobile Association and the British Medical Association on the one hand, and the traffic authorities on the other, might well be of value, if only for the purpose of revealing any weak points in the argument. The proposed rule seems to be of sufficient value to merit such discussion.

#### THE ASSOCIATION'S INTELLIGENCE OFFICER

Miss A. L. LAWRENCE, who was appointed Intelligence Officer by the Council of the British Medical Association in 1919—after serving for four years on the staff of the Central Medical War Committee, for which she was awarded the M.B.E.—has lately qualified for the diploma conferring the title of LL.B. of the University of Cambridge. Miss Lawrence was Clothworkers' Scholar at Gt. St. Mary's College, 1910-14, and took honours in Part I of the Historical Tripos, 1912. In 1914 she gained first class honours in Part II, thus obtaining the Tripos Certificate which now entitles a woman to be styled B.A. Cantab. In the recent Law Tripos examination, Part II, she attained the standard for honours, this distinction, coupled with the honours previously gained in the Historical Tripos Part I, qualifies for the title of Bachelor of Laws. Miss Lawrence's colleagues, who have learnt by experience to respect her great abilities and wide acquaintance with social conditions, are glad to know that she has received these academic distinctions and feel sure that all members of the Association will join with them in congratulating her.

## THE ARCHITECT OF THE ASSOCIATION'S NEW HOUSE.

SIR EDWIN LUTYENS, R.A.

SIR EDWIN LUTYENS, who designed the Association's New House, is one of the most distinguished of living architects. His works are to be found in almost every part of the British Empire. He was called in to advise the Government of India as to the laying out of the site of New Delhi; he is the architect of Government House and other buildings there, and of the great archway by which they are approached.

His name became a household word when he designed the Cenotaph in Whitehall, and he is one of the principal architects for the Imperial War Graves Commission. He has designed many war memorials both at home and overseas. At home we have from him the memorials at Leicester, Rochdale, York, Southend-on-Sea, Hove, Bury, Reading and Cuddah. He designed also the memorial of the Royal Naval Division in St. James's Park. Among the memorials overseas are those in Ceylon, Hong Kong, Bermuda, and Madras as well as British war memorials in France at St. Quentin, Itaples and Arras. He has built churches also, and as a domestic architect has been supremely successful both with exteriors and interiors. He is one of those who regard a garden, not as an excrescence but as part of the cantilage of the house and has given evidence of this

in the small but very perfect garden he has laid out at the south side of the South Wing of the Association's house. A very good example of his domestic style is to be seen in the small building of the Midland Bank in Piccadilly at the west corner of the courtyard of St. James's Church. To show his versatility it may be added that he has designed other business offices and also the house of the British School of Art at Rome and the picture gallery and South African war memorial at Johannesburg.

The Association's house was built before the war, but the internal decorations were never even begun; they have now been completed under his supervision, and it has been an education to watch the development of the

architect's conception through stages of apparent chaos to the final perfection. The Architectural Correspondent of the *Times* has described the exterior as "at once homely and dignified, scholarly and un-messy," and the whole building is suited to its purpose and becoming to its locality. In style, this writer continues, "it may be described as in the tradition of Wien, and slightly reminiscent of Hampton Court."

Another writer (in *Country Life*) has said of Sir Edwin Lutyens that "while the forms he uses are old he succeeds in combining them into highly original patterns. The advantage Sir Edwin Lutyens has over many of his architectural confidants is that he is content to say something new in an old language while they strain after a new language as well, this medium of expression, however, must consist of broken phrases, so their achievement has all the characteristics of immaturity." That his genius is appreciated by the members of his own profession is proved by the fact that he has received the gold medal of the Royal Institute of British Architects, and that only the other day he voyaged to America to receive the gold medal of the American Institute of Architects. He was born in 1869, was elected A.R.A. in 1913, and R.A. in 1920.

I finally, let us most gratefully say that he has shown the keenest interest in the work he has done for the Association, entering thoroughly into the special needs of its headquarters, that he gave attention to every room, conceived the bold scheme of decoration of the Great Hall, and designed the fine wrought iron screen of three gates which has been made by the Birmingham Guild and through which the King and Queen passed into the Courtyard on Monday. We will conclude by again quoting the Architectural Correspondent of the *Times*, who wrote "The best tribute to the building is to say that it is so well proportioned and so discreet in character that it gives the impression of always having been there."

# Royal Opening of the New House.

## HIS MAJESTY'S TRIBUTE TO THE MEDICAL PROFESSION.

### THE CEREMONIES ON JULY 13TH.

WAS THE FIRST TO  
HIS MAJESTY

THE New House of the British Medical Association in Tavistock Square was opened by His Majesty the King, who was accompanied by Her Majesty the Queen, on Monday afternoon, July 13th.

The opening took place with appropriate ceremonial and in the presence of perhaps the most representative gathering ever brought together in the name of British medicine. No circumstance which could give honour to the occasion was lacking. Even the one uncontrollable element, the weather, smiled upon the function, thereby relieving the minds of the organizers of their principal anxiety, for had the weather been wet the event would have been shorn of much of its spectacular effect and of a certain amount of its significance. The procession through the Court and would not have been possible, and the preliminary receptions, instead of being made at the end of the private roadway in front of the newly dedicated Gates of Honour, would have taken place in the Members' Common Room. It proved, however, to be a perfect July day, bright, but not oppressively hot—the temperature was 73° in the shade at three o'clock in the afternoon—and the red brick and white stone fittings of the New House looked then best under the blue sky, and the Gates of Honour had a particular delicacy and beauty as seen in the sunlight. The building which, with the Court, presented a scene of chaos only a few weeks or days ago, now stood finished—or at least whatever was unfinished was hidden from view—and the workmen had disappeared save for one of them who, elected for that honour by his fellows, was presented to Their Majesties. Very many of those who were present saw the New House for the first time, and expressions of admiration for one of the finest modern structures of London were heard on every hand.

The short avenue leading from Tavistock Square to the Memorial Gates was lined on each side by four Corinthian columns crowned with flowers, which gave a gay appearance to the approach. Members of the 28th London Regiment (the Artists' Rifles) formed a guard of honour under the command of Captain W. Campbell Smith, M.C. Behind them were parties of boys and girls from the Foundling Hospital for whom places had been reserved, and who greeted the Royal visitors with shrill cheers. To the south, just outside the Gates, stands had been erected for the accommodation of relatives of the members fallen in the war whose names are inscribed in the *Roll of Honour*. Some two hundred of these altogether were present at the dedication of the Memorial. In the Court and chairs were provided for about 100 members of the Association, and for representative students from every medical school in the country. By this arrangement the Court was not overcrowded, and everyone saw and heard in comfort. On the central grass plot in the centre the band of His Majesty's Grenadier Guards, by permission of Colonel B. N. Seigison Brooke, C.M.G., D.S.O., rendered a programme of music under the direction of Lieutenant G. N. Miller, L.R.A.M., and in the western ambulatory of the Great Hall a string orchestra composed of musicians from the same band also gave selections. The music, like the other proceedings, was transmitted by means of microphone and loud speakers from the Court to the Great Hall, while loud speakers outside the Great Hall enabled everybody within a big radius to hear what was going on within.

From one o'clock onwards a constant succession of motor cars entered from Tavistock Square bringing members and guests. Some of these came in academic dress or uniform, and others robed in the building on arrival. The interior of the Great Hall as it gradually filled presented a remarkable appearance. Almost every occupant of the seats in the body of the Hall wore academic costume, and the massing of the colours, scarlet predominating, toned well with Sir Edwin Lutyens's colour effects of the walls and the roof. The banners representing the cities in which Annual Meetings have been held, and above these the flags of the Dominions, added to the brilliancy of the scene under the gilt steel arches. The dais, in the foreground of which two thrones had been placed, was decorated with hydangeas.

In sending out the invitations to the ceremony in the Great Hall the object had been to illustrate the solidarity of the medical profession and to bring together a representative gathering of members of the Association. Several veterans in the service and membership of the Association were present. One octogenarian was Dr. Michael Bevelley, who was secretary of the Annual Meeting of the Association at Norwich in 1874, and a member of Council for many years; another was Dr. James Stewart of Lambeth, a third who was presented to Their Majesties was Dr. G. W. Crowe of Worcester, secretary of the Jubilee Meeting held in that city (the birthplace of the Association) in 1882. Places were found for those who have held the highest offices in the Association in former years—secretaries of Annual Meetings, and former central officials of the Association. Others were present as members of the General Medical Council and the Dental Board, medical members of Parliament, representatives of universities, colleges, and medical corporations, representatives of medical and allied societies in the British Isles, the Dominions,

and foreign countries, also the heads of the Medical Departments of the Army Services. The non-medical persons present included representatives of Government departments with which the Association is frequently in contact, the High Commissioners for the Dominions, members of certain local authorities, including the City Corporation, the London County Council, the Bath City Council, and the Borough Council of St. Pancras, the borough in which the New House is situated. Certain ladies to whom the Association owes special consideration, such as Lady Horder, Mrs. Lord Trevelyan, and Mrs. G. F. Halsey, also had places assigned to them in the body of the Hall. The morning seats—some 260 in number—were filled by official representatives of Divisions and Branches in the United Kingdom, and by members of the Association who had been fortunate enough to secure places by ballot. The gallery at the south end was allotted to ladies—wives of members of the Reception Committee, of Chairmen of Standing Committees, and of other members of Council.

#### DEDICATION OF THE GATES

At five minutes to three the Most Reverend His Grace the Archbishop of Canterbury (Dr. Randall Davidson), who was wearing his Convocation robes and was accompanied by his chaplain, proceeded to the outer side of the Gates of Honour which were locked and a solemn but brief Service of Dedication was held.

Humphry Rolleston, Bt.) the President of the Royal College of Surgeons (Sir John Blund Sutton, Bt.), Lord Dawson of Penn, G.C.V.O., M.D., Sir George Newman, K.C.B., Sir Edwin Lutwens (the Architect of the building) and Mr. J. J. Wilton (the contractor). On the other side of the Gates other members of the Council were grouped. The embroidered gowns of the

#### DEDICATION OF GATES OF MEMORANCE BY THE ARCHBISHOP OF CANTERBURY

Behind the Archbishop are standing the Architect Sir Edwin Lutwens, the Chairman of the Representative Body, Dr. H. B. Brackenbury, the Chairman of Council, Dr. R. A. Bolam, and the President of the Royal College of Physicians, Sir Humphry Rolleston.

Those standing with the Archbishop were the President of the Association (Mr. J. Basil Hall, M.Chir., F.R.C.S.), the Chairman of Council (Dr. R. A. Bolam, M.D.), the Chairman of the Representative Body (Dr. H. B. Brackenbury), the Treasurer (Mr. A. Bishop, M.Chir., F.R.C.S.), the President of the General Medical Council (Sir Donald MacAlister, Bt.), the President of the Royal College of Physicians and Regius Professor of Physic at Cambridge (Sir

Presidents of the two Royal Colleges in particular gave a vivid touch to the scene.

The service began with the hymn, 'O God, our help in ages past,' led by the band of the Grenadier Guards.

The CHAIRMAN OF COUNCIL then, addressing the Archbishop, said:

In the name of the British Medical Association I ask Your Grace to dedicate these Gates, which have been

made and placed here in memory of the Members of our Association who laid down their lives in the Great War

Photo]

OPENING OF THE GATES

[The Times

The Archbishop, before dedicating the Gates, offered the following prayer

O God and Father of us all, Who didst send Thy Son Jesus Christ to be the Great Physician of our souls and bodies, we praise and magnify Thy Holy Name for the work of the surgeons and doctors who in the Great War saved their fellows even unto death. As in thankfulness we dedicate to thee, to Thy glory and their memory, these Gates, so we pray that all who pass through them, both coming in and going out, may also remember that it is thine not to be ministered unto but to minister. Through the same Jesus Christ our Lord. Amen

The Archbishop, advancing to the Gates, said

To the glory of God and in memory of those Members of the British Medical Association who gave their lives in the Great War, we dedicate these Gates. In the name of the Father, and of the Son, and of the Holy Ghost. Amen

Sir Edwin Lutyens, the Architect, presented the key of the Gates to His Grace, who unlocked and opened them amid an impressive silence. The Gates being open, the Archbishop said

In gratitude and hope we open the Gates. *Dominus custodiat exitum et introitum*

The ceremony concluded with the singing of "Abide with me"

## ARRIVAL OF THEIR MAJESTIES

After an interval of about five minutes cheers were heard in the distance, and punctually at ten minutes past three Their Majesties drove up in semi-state in an open landau drawn by four horses and preceded by outriders. Accompanying them was the Right Hon. Neville Chamberlain M.P. (Minister of Health). A second landau contained the Dowager Countess of Minto, lady in waiting to Her Majesty, the Lord Somers, gentleman in waiting, Major the Hon. Richard Molyneux, groom in waiting, and Captain the Hon. Alexander Hardinge, equerry and assistant private secretary. The King pleased everyone by his appearance of health and vigour. The Queen was most becomingly dressed in pale mauve, with a lace scarf, and carried a sun shade the exact colour of her dress.

Immediately on Their Majesties' arrival the Royal Standard was broken at the mast above the main entrance, and the National Anthem was played by the band of the Artists' Rifles. The Minister of Health presented to Their Majesties the President of the Association and the Chairman of Council. The King then inspected the Guard of Honour of the Artists' Rifles, and while His Majesty was so engaged the Queen occupied the President and Dr. Bolam in conversation, obviously expressing her admiration for the external appearance of the building. Dr. Bolam indicated to Her Majesty, and also to the King, who had by this time returned from the inspection of the guard of honour, the structural developments which will take place in the course of time and the extensions which will be possible. Their Majesties then came to the centre of the roadway and spent some moments regarding the newly opened Memorial gates.

The Chairman of Council then presented to the King and Queen the Chairman of the Representative Body, the Treasurer of the Association, Sir Donald

## ENTRY OF THEIR MAJESTIES

Left to right: Chairman of Council, The King, The Queen, the President (Mr. Basil Hall)

[Central Press

Sir Edwin Lutens, and Mr. F. J. Walton, Miss  
C. M. Loris Scott, the little daughter of the Finan-  
cial Secretary, betraying no more than a becoming  
mount of nervousness, presented a beautiful bouquet  
of Malmaison carnations and lilies to Her Majesty,  
who graciously received it, and shook hands with the  
young giver.

A procession then formed in the following order,

proceeding through the Court and to the vaulted  
passage underneath the Great Hall.

The King, escorted by the Chairman of Council.

The Queen, escorted by the President of the Association.  
The Minister of Health and Ladies and Gentlemen in  
attendance.

The Archbishop of Canterbury.

The Chairman of the Representative Body and the other  
gentlemen who had just been presented.

[1106]

ROYAL PROCESSION THROUGH THE COURT OF HONOUR

[Topical 1108]

The procession entered the Members Common Room on the right of the passage. Here the members of the Reception Committee were assembled, and the Chairman of Council made a number of other presentations to Their Majesties. It had been intended that the first of these should be Dr F G Thomson of Bath, the President Elect, but, to the great regret of all, Dr Thomson was unable to be present owing to a severe attack of pleurisy. The following presentations were made:

- Mr C P CHILDF, F R C S, Past President (Portsmouth)
- Dame LOUISA ALDRICH BLAKE, M S, M D, Dean of the London School of Medicine for Women
- Miss FRANCIS IVENS, M S, President of the Federation of Medical Women (Liverpool)
- Dr R WALLACE HENRY, Past Chairman of the Representative Body (Leicester)
- Dr C O HAWTHORNE, Deputy Chairman of the Representative Body (London)
- Dr J A MACDONALD, LL D, Chairman of the Journal Committee (Taunton)
- Mr JENNER VERRALL, LL D, Chairman of the Dominions Committee (Leatherhead)
- Dr R LONDON DOWNS, Chairman of the Central Ethical Committee (Teddington)
- Mr H S SOUTAR, F R C S, Chairman of the Hospitals Committee (London)
- Dr H G DAIN, Chairman of the Insurance Acts Committee (Birmingham)
- Mr J B TURNER, F R C S, Chairman of the Medical-Political Committee (London)
- Mr RICHARD LUTHER KCMG MP, Chairman of the Naval and Military Committee (Derby)
- Dr S MORTON MACKENZIE, Chairman of the Organization Committee (Dorling)

- Dr T RIDLEY BAILEY, Chairman of the Public Health Committee (Bilston)
- Dr JOHN STEVENS, Chairman of the Non Panel Committee (Edinburgh)
- Dr E K LE FLEMING, Chairman of the Conference of Local Medical and Panel Committees (Wimborne)
- Mr THOMAS HORDER, Bt M D, Chairman of the Post-Graduate Committee (London)
- Mr LEWIS J MACLEAN, M D, Chairman of the Puerperal Morbidity and Mortality Committee (Cardiff)
- Dr CHARLES BUTTAR, Member of the Reception Committee (Felstead)
- Mr COMINS BERKELEY, M Ch, President of the Metropolitan Counties Branch, the largest Branch of the Association (London)
- Mr G E STAPLES, General Foreman of the Building Operations
- Mr W REYNOLDS, Elected Representative of the Workmen
- Mr DAWSON WILLIAMS, LL D, Editor of the *British Medical Journal*
- Dr ALFRED COX, Medical Secretary of the Association
- Mr L FERRIS SCOTT, F C A, Financial Secretary and Business Manager of the Association
- Mr W E HEMPSON, Solicitor of the Association

The presentations over, Their Majesties ascended the stairs to the Great Hall, which they entered from the southern end, and walked the length of the central aisle to their places on the dais. Most of those who had been already presented took their places behind them.

The company being seated, the CHAIRMAN OF COUNCIL read the following loyal Address of the British Medical Association to Their Majesties, and the KING then read the Reply, also printed in full, the whole of those present standing.

## Address of the Association

MAY IT PLEASE YOUR MAJESTIES —

On behalf of the members of the British Medical Association we offer our grateful thank to Your Majesties for graciously consenting to perform the opening ceremony of the new House of the Association. We recall with pride and pleasure that His Majesty King Edward the Seventh in 1900, when Prince of Wales, graciously accepted the Honorary Membership of the Association, that on succeeding to the Throne he further honoured us by becoming Patron of the Association, and that Your Majesty did graciously consent to occupy that office on your accession to the Throne.

The British Medical Association was founded at Worcester in 1832 by Sir Charles Hastings, an eminent and public spirited physician, whose memory we desire proudly to honour on this auspicious day. The Association from its beginning has had for its objects the promotion of the medical and allied sciences and the maintenance of the honour and interests of the medical profession. In pursuance of these aims the Association has striven to maintain the great traditions of the medical profession and to interest every one of its members in the advance of the science and art of medicine, having always in mind that the members of our profession are not only guardians of the interests of the individual patients committed to their charge, but, collectively, have a duty to the community in the promotion and protection of the public health.

In its work for the advancement of medical science the Association has for many years spent about £1,000 a year on scholarships and scientific grants which have been the means of encouraging many young doctors to pursue medical research. Our Annual Meetings, at which the progress of the various branches of medicine is reviewed, give opportunities to those who have made new discoveries or evolved new ideas to place them before their colleagues for discussion, and throughout the year in the length and breadth of the land, local units of the Association carry on the education of our members and provide for them, in some measure, that post-graduate study which is so essential for progress and which we regretfully recognize has not yet been organized and developed in this country as it ought to be. In addition, the Association publishes the *BRITISH MEDICAL JOURNAL*, which is recognized as among the leading medical journals of the world, has the widest circulation of any in the British Empire, and is one of the main instruments of the Association in the instruction of its members.

Not least among the activities of the Association are those which concern the relationships of the practitioner to his fellows and to the community, and the standard of ethics rightly to be observed in a liberal profession.

From the representative character of the gathering before Your Majesties to-day it may be seen how far the Association has succeeded in its efforts to enlist the support of all sections of the profession. Among its members, anxious to serve its great objects, there have always been, from its inception to the present day, the most eminent men and women in the profession. It is all embracing in its ranks are the general practitioner—the mainstay of the Association, as he is the first line of defence on which the public relies in accident and disease—the physician, the surgeon, the specialist, the teacher, the public health officer, the laboratory worker, and in all ranks the Association has no more loyal supporters than its women members, now numbering some 2,250. May we say on their behalf how greatly we appreciate the presence to-day of Her Majesty the Queen, who has shown in so many ways her interest in the education and special work of medical women.

We would point with pride to the fact that the Association's membership is world wide, that many of our most successful Branches are in Your Majesty's Dominions over the sea, and that we are favoured on this great day in the Association's history with the presence of eminent medical representatives of Canada, Australia, New Zealand, South Africa, and India, together with many from the Colonies and Dependencies. In recent years distinguished members of the Association have officially visited South Africa, Australia, and Canada and we are assured that these delegations have played an important part in cementing the bonds of union of the profession throughout the Empire. Our relations with kindred societies in this and other countries are cordial and mutually helpful, as is shown by the presence on this occasion of representatives of almost every medical organization in this country, of representatives of several great medical associations of European countries, and of an important delegation from the American Medical Association.

Your Majesties have seen at the entrance to this House the Gates we have erected to the glorious memory of the 574 members of the Association who gave their lives for their King and Country in the Great War, and it is hoped that you will graciously inspect the *Book of Honour* in which their names have been engrossed with loving care and artistic beauty by Mr. F. G. Hallett, O.B.E. The Association records with pride that by means of its organization in local units throughout the United Kingdom it was able during the Great War to serve the State in many ways, but chiefly by ensuring the supply of doctors for the Services, having due regard to the interests of the civil population at home.

The House which we now ask Your Majesty graciously to declare open is the work of Sir Edwin Lutyens, R.A., who designed it and after its use by the military authorities during the War, has adapted it to the use of our Association. In it we shall have greatly extended opportunities for usefulness to our members to the profession of medicine and to the community at large. It will be our endeavour so to use this House and these opportunities as to be worthy of the intentions of our Founder, of the past history of the Association, and of the encouragement which Your Majesties have given us by your presence here to-day.

In asking Your Majesty to declare this House open we desire to express the loyalty of our members to Your Majesties, and to utter the fervent hope that Your Majesty may long be spared in health and strength to preside over the destinies of our great Empire.

VIEW OF GREAT HALL DURING HIS MAJESTY'S REPLY TO THE LOYAL ADDRESS OF THE ASSOCIATION

[Topical Press

### His Majesty's Reply

I AM pleased to come here to-day, accompanied by the Queen, to open the new and admirably designed House of the British Medical Association. We have always taken a sincere interest in the science and practice of medicine and surgery, and I am proud to have succeeded my Father, King Edward, as Patron of your Association.

Since its foundation, nearly a century ago, by Sir Charles Hastings, your Association has shown a remarkable increase both in membership and usefulness, and the well informed and constructive criticism that it brings to bear upon the evolution of your profession is of great value. The British Medical Acts wisely restrict admission to the *Medical Register* to those who have been trained in accordance with prescribed regulations and have passed the necessary qualifying examinations. At the same time vigilance must always be exercised in order that your profession may keep abreast with the advance of science, and also preserve a high standard of professional practice and ethics. The noble purpose, the character and the skill of those engaged in the art of healing, are your most precious traditions, and you do well jealously to watch over such attributes.

I am glad to notice your recognition of the advantages of post graduate study, in which my brother in law, Lord Athlone, a former Chairman of the Middlesex Hospital, has taken such a deep interest.

The reference in your Address to the ever widening scope of the medical practitioner in relation to the general health of the people is most satisfactory, and I have followed with sympathy the negotiations for securing smooth and effective co-operation between him and the public medical services. The welfare of my people at home and throughout the Empire largely depends upon an efficient and well organized health administration. The protection of maternity, the care of the child, a sanitary home and workshop, the safeguarding of the food supply, properly designed defences against infection and prevalent disease are all matters of vital importance. There is also an opportunity for the medical practitioner in his everyday practice to be a missionary and teacher of public hygiene and of personal health.

On behalf of the Queen, I thank you for your allusion to her interest in the education and work of medical women, and on this occasion we are both glad to express our appreciation of their activities in all branches of medicine.

I am especially pleased to learn of the close and friendly relations maintained between members of your profession in all parts of the Empire, and I heartily welcome here to-day representatives from the Dominions beyond the Seas and also from European countries and from the American Medical Association.

At this point the King was handed by the Architect a Master Key in gold, and he concluded his reply with the words:

I have much pleasure in declaring open this House of the British Medical Association, and I congratulate its members upon the possession of their new and dignified home.

## FURTHER PRESENTATIONS

The whole of the Address was heard by those in the grounds outside. The King's voice as transmitted by the loud speakers, was heard with astonishing clearness, and every syllable sounded out not only in the Court-yard but in the street beyond. Those outside the building joined with those within in the long-continued applause with which the Royal declaration that the building was open was greeted.

[Phot.]

HIS MAJESTY DECLARING THE NEW BUILDING OPEN

[Topical Press]

On the left behind the Chairman of Council is the Minister of Health. On the right behind the Queen are Sir Donald MacAlister, President of the General Medical Council, and the Chairman of the Representative Body.

Subsequently to these addresses some further presentations were made as follows:

- Dr G. W. CROWE of Worcester, one of the oldest Members of the Association who lives in the house formerly the residence of the Founder, Sir Charles Hastings
- Dr C. E. DOUGLAS, Chairman of the Scottish Committee
- Dr J. S. DAPLING, Acting Chairman of the Irish Committee
- Dr W. E. THOMAS, Chairman of the Welsh Committee.
- Dr W. A. ROBERTSON, Representative of the Australian Federal Committee
- Dr J. BANCROFT ANDERSON, Representative of the South African Committee
- Dr C. F. MACGRIPE, Representative of New Zealand
- Lieut.-Colonel L. W. C. BRADFIELD, I.M.S. Representative of the Indian Branches
- adapted to the use of the Chairman of Council of the Canadian Association
- endeavour so to use the Representative and Past President of the past history of the Medical Association
- your presence here to day
- In asking Your Majesty to represent France
- to Your Majesties and to u
- strength to preside over the
- Representative of Sweden
- Representative of Norway
- Representative of Denmark

## INSPECTION OF THE ROLL OF HONOUR

Their Majesties, accompanied by the Archbishop of Canterbury, the Minister of Health, and the members of the Reception Committee then descended to the Library, where they inspected the Association's Roll of Honour. Mr I. G. Hallett, Secretary of the Examination Board of the Conjoint Royal Colleges, who has illuminated the Roll, was presented.

Their Majesties asked Mr Hallett how many hours he had spent on the task and were informed about 430. The King especially admired the gold work, and Mr Hallett explained that his talented assistant, Miss M. Baker, was responsible for that part of the decoration. Dr J. A. Macdonald, Chairman of the Journal Committee, then presented to Their Majesties a handsome copy of the Roll of Honour bound in purple levant morocco, and padded. The size of the pages was the same as that of the present Supplement, and every page was most carefully and beautifully reproduced by photo-mechanical means. The volume was graciously accepted and delivered into the charge of the Treasurer of the Association who undertook to convey it to the Palace.

## THE LIBRARY

Mr Walter G. Spencer, M.S., F.R.C.S., the Honorary Librarian, and Mr Honcman Librarian, were also presented, and Mr Spencer pointed out to Their Majesties some of the more valuable books in the Library. The Queen showed great interest in the shelving arrangements.

In one corner of the Library Sir John Bland-Sutton, P.R.C.S., had arranged some interesting specimens which he had brought from the Museum of the Royal College of Surgeons.

The exhibits which took the King's attention most, and which Sir John Bland-Sutton explained, were the artificially shrivelled heads of three Indians from the dense forest region of the Amazon. The curious heads, contracted to perhaps one-fourth of the natural size, still had attached to them the masses of long black hair. Among other objects which caught the King's eye were the skull of a Bengalese child with a second imperfect skull attached to the anterior fontanelle, a portion of a tusk (presumably an elephant's) with a spear embedded in the pulp cavity and a layer of secondary dentine around the weapon, formed so as to wall it off from the remainder of the pulp, a human heart showing extensive laceration and loss of substance of walls of both ventricles about the apex, produced by an armour-piercing bullet used against aeroplanes, also the missile which did the mischief, a stuffed Japanese pheasant, a hen, twelve years of age, with partly assumed plumage of the male, the heart of a calf pierced by pins, thorns and twigs of witch-hazel, an example of sympathetic magic, two portions of the small intestine (probably of Napoleon I), with growth-projecting above the mucous membrane, the long blade of a bayonet which was removed from the erector spinae muscle some days after its introduction, and after the wound of entry had healed, and a complete cast of the stomach successfully removed by operation from a woman who was in the habit of eating the fibre of coco nut shells. When

he was shown a further exhibit of this kind—an immense human bill taken after death from the stomach of an alligator—the King remarked that he was familiar with the formation of these human bills. The King and Queen spent quite ten minutes over these specimens, and the King smiled at some of the zoological curiosities.

Before leaving the Library the King and Queen, using a quill pen, wrote their autographs on vellum in the Visitors Book, the signatures immediately following being those of the Minister of Health and Sir Donald MacAlister, and the Presidents of the two Royal Colleges.

### VISIT TO GARDEN AND ADJOINING SCHOOL

An event which was not on the programme then took place, the King and Queen making their way through the South Wing of the building, where the Council Chamber is situated, and out into the pleasant Council Garden at the rear, with its semi-circular terrace and oval pool. In the grounds adjoining, some 120 boys and girls of the Mary Ward (Miss Humphry Ward) School in Tavistock Place, better known as the Passmore Edwards Settlement, were assembled. These are children whose physical (not mental) defects make it impossible for them to go to an ordinary elementary school, and they are brought from various parts of London in ambulances each day to receive instruction in these pleasant surroundings. Their Majesties asked many questions of the head teacher, Miss King, and spent five or ten minutes among the delighted children. Returning to the building, Their Majesties were reminded of the Dickensian associations of this particular part of the site, of which an interesting account is given elsewhere in this issue by Mr. Munhead Little.

### DEPARTURE OF THEIR MAJESTIES

The King and Queen emerged from the South Wing at the western door and made their way to their carriage, which was drawn up in the Courtyard. The members of the Reception Committee and the various distinguished persons who had greeted Their Majesties on arrival assembled to give them a fitting send-off. Three hearty cheers were raised for the King, and three more for the Queen, and the National Anthem was again struck up as the procession made its way through the Gates of Honour.

Their Majesties left at five minutes past four, after a stay of fifty-five minutes.

The company in the Great Hall did not leave their places until after Their Majesties' departure. Afterwards there was a general inspection of the building and tea was taken in the Members' Common Room, while music was continued in the Courtyard and in the Great Hall for a further hour and a half.

A word should be said in praise of the police arrangements, which, under Inspector Cole, worked to perfection. Nowhere was there any crowding or jostling and the two ceremonies were carried through with entire success, thanks to the forethought of the committee in charge of the arrangements and to various officers and officials of the Association.

Acknowledgement should be made to Major E. W. Paget, C.B.E., Liaison Officer of the Home Ambulance Committee of the Order of St. John and the British Red Cross Society, for his courtesy in arranging for the provision of a detachment of nurses, who attended during the afternoon ceremonies.

DEPARTURE OF THEIR MAJESTIES WITH THE MINISTER OF HEALTH

The following gracious message from Their Majesties was received by the Chairman of Council on the morning after the Opening Ceremony:

### BUCKINGHAM PALACE

July 13th, 1925

DEAR DR. BOYD,

The King and Queen desire me to let you know what pleasure it gave Their Majesties to open the new home of the British Medical Association to-day, and to have an opportunity of inspecting this splendid building.

Their Majesties congratulate you on the excellence of all your arrangements, and thank you and all who co-operated with you for the trouble which you took to make the visit a success.

Yours sincerely,  
A. H. L. HARDINGE

R. A. BOYD, Esq.,  
M.D., F.R.C.P., O.B.E.

### EVENING ENTERTAINMENT

#### PRESENTATION OF GIFTS

At night, from 8.30 to 12.30 a brilliant entertainment took place, for which invitations had been issued to one thousand guests. The grounds both the courtyard and the terraced garden behind the South Wing were illuminated with fairy electric lamps, and the House was open for inspection. Once again by means of loud speakers the whole neighbourhood shared to some extent in the festivities.

The guests were received at the top of the staircase of the South Wing leading to the Great Hall by the President and Mrs. Basil Hall. Invitations were sent to all who were present in the afternoon together with their ladies, and almost every notable person in the medical world appeared to be present. A bouquet was presented to Mrs. Basil Hall early in the proceedings. Musicians from the band of His Majesty's Grenadier Guards again gave selections, Mr. Hubert Eisdell and Mr. Harold Williams contributed songs,

and after the presentations Miss Maudie Scott was permitted to sing.

Opportunity, which was not possible in the afternoon was taken for the conveyance of messages and gifts to the Association from Overseas Branches and other medical bodies.

#### MESSAGE TO PRESIDENT-ELECT

The PRESIDENT, before calling up the three delegates and ladies and gentlemen, I have some official duties to perform this evening, but before I enter upon them I ask you to allow me to move a vote of sympathy to Dr F. C. Thomson of Bath, who, as you know, is the President-elect, and who would have entered upon his duties as President next week. Dr Thomson, unfortunately, is suffering from pleurisy, and has telegraphed to us that it will be quite impossible for him to undertake the duties of incoming President at our Bath Meeting. I suggest therefore, that we send a vote of sympathy to him, saying how much we share his disappointment, and wishing him a speedy recovery. (Applause)

Dr BRICKENBURY: I second the motion proposed by the President. It is, of course, a great disappointment that Dr Thomson has not been able to be with us to-day, and that he will not be with us at Bath. It must be a great disappointment to him also, but if I know anything of him I think the greatest disappointment to him will be that he has disappointed us. In these circumstances it will be a nice thing from us and a thing grateful to him if we send him a vote of sympathy, coupled with our highest hope that he will very soon recover his usual health.

The vote of sympathy was carried, and the PRESIDENT said that he would send it personally.

#### PRESENTATION OF DELEGATES

The PRESIDENT: My next duty is to welcome the many representatives who have come from across the seas—those from our Branches and from kindred societies throughout the civilized world. Although certain representatives of the Overseas Branches had the honour of being presented to Their Majesties this afternoon, those bring no news complete the total list of members of our great fraternity who have come across the seas to rejoice in this occasion. There are at the present moment in this room representatives of the great Dominions and of India of Ceylon, Egypt, British Guiana, the West Indies, Sierra Leone, Hong Kong and China, Mesopotamia, Natal, and Uganda. (Applause) Besides representatives of the Overseas Branches, we have with us Professor Primrose, of the Canadian Medical Association. (Applause) I have mentioned him separately, but I regard him as one of us, not only on account of our affiliation but also on account of the very kind hospitality our Canadian brethren have exhibited towards your President. (Applause) We have also representatives of the great American Medical Association. I am not sure whether Dr W. Haggard, the President has yet arrived, but we have with us Dr de Schweinitz who was President of that association in 1922-23 and Dr Howard Fox. (Applause) I can assure them that we thank them most sincerely for coming. We have also the privilege of welcoming representatives from France, Holland, Denmark, Norway, and Sweden. Norway sent to us two very welcome guests, Dr Petersen and Dr Koppang who represent the great Norwegian professional society. To each and all our guests I extend a most cordial and sincere welcome on behalf of the British Medical Association. We rejoice to have them with us and we hope that on their return they will convey to their brethren our very hearty good wishes. (Loud applause)

I will now read out a list of those Divisions which have already sent or are in course of sending a Divisional flag for the Great Hall. Some of these flags as you see have already been hung. Others are due to arrive very shortly. The Divisions are Worcester, Birmingham, Oxford, Manchester, Liverpool, York, Sheffield, Peterborough, Nottingham, Edinburgh, London, Newcastle-on-Tyne, Cardiff, Bournemouth, Carlisle, Montreal, Leicester, Toronto, Aberdeen, Glasgow and Bradford. (Applause)

The MEDICAL SECRETARY then referred to a number of messages of congratulation which had been received. One was from the Linnæan Medical Society offering sincerest

good wishes. The Académie de Médecine of Paris was unable to send a representative but added that its good wishes might be conveyed. That morning two cablegrams had come from Australia, one from the Australian Federal Committee offering congratulations and congratulations, and the other from the Medical Journal of Australia.

#### CHIT OF PRESIDENT'S CHAIR FROM AUSTRALIAN BRANCHES

Dr W. N. ROBERTSON, C.B.E., Vice-Chairman of the Australian Federal Committee, said: I am very proud to have come 13,000 miles to carry the message of goodwill and affection from the Branches of the British Medical Association in Australia to the present Association at Bath. (Applause) When the Federal Committee, of which I have the privilege of being a member found that this important function was to take place they said, 'We must do something to commemorate this occasion and put up an established memorial.' We decided eventually to give the President's chair, which you now see on the platform and we wish it well and think sit upon at every meeting of the great Association here. (Loud applause) When the powers that be were good enough to cable over and invite some of us to be present to-day it unfortunately happened that Sir George Syme, who is President of our Federal Committee, was unable to come. He is presiding over a Royal Commission from which we expect great things in the way of the improvement of the health of the people of Australia. Therefore it fell to my happy lot to come over in his place. I feel very diffident about making a speech. Many and many a night I have more or less in dreams, made the most brilliant speeches for this present occasion. But as I stand here I have forgotten all those beautiful speeches. I can only express in my poor way the wonderful loyalty of the Branches of Australia. (Loud applause) We are far from you geographically, but very near you in spirit. (Applause) I come from the most distant State of all—Queensland—the most distant Branch of the British Medical Association in the world barring New Zealand. On my way here my ship called at every Australian port, and as we touched the various State capitals which are the headquarters of Branches I was made aware how strong and deep is the loyalty of Australia. They treated me like a royal envoy, not for my own sake, but because I was their messenger to you. All that wonderful kindness was then meant for me to convey to the Association at home. At Melbourne I asked Sir George Syme what I should say, and he said, "Stress the Imperial idea." That is exactly the spirit in which, in the hour of need, our boys rose up as one man to come to the help of the King and the Empire. That is the feeling which is manifest in the British Medical Association in Australia. The members of the Association out there, if I may due to say so, are as loyal or even more loyal, to the Association than the men here at home. We are for ever loyal to this dear old parent Association which has set such glorious ideals before us. I am very proud to be here to-night, and I beg you to accept this gift from the Branches of Australia as a token of their goodwill, their affection, and their loyalty to the British Medical Association. (Loud applause)

Dr Robertson then handed over the chair, and read the inscription on the back, which is printed, together with a sketch of the chair, at pages 132-3.

The PRESIDENT, after taking his seat in the chair, said: We have yet another gift to receive from Australia, and I will reply for them both at once.

#### A GIFT FROM TASMANIA

Dr STODART BURN, representing Tasmania said: I have very great pleasure indeed, on behalf of the Tasmanian Branch, in offering to the President the gift of a chairman's mallet. It is a very small gift from a very small Branch, 12,000 miles away. I am privileged to be the first person to present anything to the President after he is seated in his chair. (Loud applause)

The PRESIDENT: Dr Robertson and Dr Barr, I will address you simultaneously, because there is one feature in common in both your gifts. We value them, not merely on account of their intrinsic worth, but on account of the spirit in which both have been given. It is just that sort

occurred it has invariably been after the dissection operation, it has seldom happened, to my knowledge after the ordinary guillotine operation. The chance of infection through the Pasteur-Chamberlain tube is much greater in the dissection operation.

I say that it should not be performed as a routine, and never where the child is sent out of hospital the same day or even within the next day or two—I am, etc.,

ARTHUR M. BIRROD,

Aural Surgeon, Paul W. St. Joseph's Hospital  
and to the L. E. O. H. at South  
Comm. for L. E. O. H. at South

Chief, or Jerech

## ROYAL NAVAL VOLUNTEER RESERVE MEDICAL SERVICE

SIR—The letter of "R.N.V.R.," published in your issue of July 9th (p. 80), calls attention to the very marked lack of official appreciation of the war service of the medical branch. One might almost suppose that the policy of the "frozen mitt" had been deliberately adopted by the Admiralty towards these officers. I can quote my own case as an example. After being ten years in the Reserve, five of which were spent on active service, I retired. A vacancy occurred in my district, and I submitted my name for appointment as Admiralty surgeon and agent more for sentimental reasons than any other, as the financial return would have been "nothing. Through there were no other applicants who had served, my submission was abruptly turned down. This sort of treatment is scarcely an encouragement to the service of one's country, which is the service in the Reserve. There was not even an official note of thanks for our services when we were demobilised—I am, etc.,

July 1, 1927

EX P. N. V. R.

## Medical Notes in Parliament. [FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons has just passed the Finance Bill through Report and Third Reading, and discussed Scottish Estimates.

### Landlord and Tenant (No. 2) Bill

Standing Committee B of the House of Commons devoted considerable time on July 12th to consideration of the Landlord and Tenant (No. 2) Bill. An amendment to include in the bill premises used for carrying on a profession was debated and was ultimately withdrawn in favour of a new proviso restricting compensation to improvements in such premises.

Sir Richard Lee moved to insert in Section 1 of Chapter 12 after the words "business, the word or profession. He said that he understood that the Government did not intend to oppose this amendment if there was a definite expression of opinion on the part of a considerable number of persons that the provisions of the bill should extend to professional premises. He desired to speak especially of the medical profession. There was a body of opinion in that profession in favour of it, and included The British Medical Association had passed a resolution to that effect. There was also a considerable demand from dentists to be included and he was glad that the Government through the Home Secretary had promised that this matter should be left to the free vote of the Committee. The relation of a doctor or a dentist to the premises where he did his work was important and if he was turned out it was just as important to him as to a housekeeper. A doctor might have to improve his premises for professional purposes. In some instances he had to build premises under the direction of the Insurance Act Committee to provide suitable accommodation for his patients and he often had to build a garage solely for the purpose of his practice. Such improvements must be of value to the landlord in letting it to a doctor or on another occasion. There was therefore no reason why professional premises of this kind should not be added to the bill on the same footing as shops and houses. He moved that the bill on the same footing as shops and houses.

Mr. MacLaren and he was sure that the Home Secretary would agree that there were certain people who might be termed professional men who would suffer severely under the strict lines of the original bill. He therefore wished to support the amendment.

Sir P. Pilditch hoped that both the Home Secretary and the Committee would be careful in giving support to this amendment because it meant a very large extension of the bill. The people made in its favour had referred mainly to doctors, but what he intended to say applied much more largely to other classes of professional men. He did not know whether the amendment would open the door to professional men getting compensation for physical improvements made and to the whole question of compensation for goodwill. There was something to be said in the matter of improvements but nothing with regard to goodwill. The theory that it was possible for a professional man to have

acquired the class of goodwill which this bill was going to cover was absurd. The goodwill to be compensated or was goodwill which remained appurtenant to the premises. Could anyone imagine that any doctor or other professional man could have left the premises? The great extension in the amendment would bring about was not justified because it would do away with the real intention of the bill which was to extend to extend to private residences. In Harley Street and other similar streets there were four doctors might come on the premises in the same house. Even if the bill would do this amendment would have a claim for compensation not only for improvements but also for goodwill and they would get a set of circumstances which would make the work of the tribunal almost unworkable.

Major Crawford said that Sir P. Pilditch seemed to have advocated a very dangerous principle. The Committee was not sitting to help particular classes of people but to establish certain principles of law and it more than one class came under the same principle it should be extended to them all. What was the difference between the position of the professional man such as the doctor and the retail shopkeeper in respect to this principle?

Mr. G. Jones said that it was right that a man who put more on improvement should be compensated and that a man who built up a good will should also be compensated. He could not see why that principle could not be extended to the professional man. The amendment was an attempt to help doctors and other professional men and to prevent a man from being victimised in the way that tradesmen had been victimised in the past.

Mr. Womersley said that he invariably experienced that when a man required a return premium or a return for the premises the owner asked for more than he would have asked for if the premises had been a private residence. He had handled many cases of this kind. There had been a row of houses and when a doctor came along looking for premises to carry on his profession he had to put up with a lot of trouble and the owner would not be compensated to the extent that the tribunal might decide.

Sir M. Manninghull Butler said that no distinction had to be given of a profession. The profession of a doctor was one in which the return was a very strong case for compensation for improvement. In regard to the question of goodwill in connection with the medical profession an entirely new view was put forward to what was a doctor's goodwill. Was the principle which was put forward to be looked upon as goodwill? If the doctor was unable to get a fresh lease was he to get compensation for what he had paid for his practice? He thought that that was a view that some doctors were inclined to take. It was in a country district a landlord knew that if he let premises to a doctor he might be rendered liable to pay the doctor the whole of the amount that he paid for the practice. The doctor would find it difficult to get a house. If the whole of the premises was going to be embraced in the bill could the landlord be asked to be given to the many different and conflicting views as to what the goodwill not only of a doctor but an auctioneer or a barrister? It would be. If the amendment were made to allow the payment of compensation for improvement made by doctors and dentists it would have the support of the law. It opened up the question of compensation for all the various trades and forms of goodwill throughout all the various professions which were not even yet defined. The bill might be overruled and made unworkable. It was therefore to be the result of the improvement the amendment he should vote against it.

The Home Secretary said that he would read the Committee to decide one way or the other on the terms of the amendment but he would put his view before the Committee. He thought that the amendment clearly brought all professional men both for improvements and for compensation within the scope of the bill. That was carrying the bill considerably further than in the original bill. Having been a professional man himself for a good many years he thought that the type of goodwill in a professional man's business was not the same as in a tradesman's business. He had more from one part of London to another and it had made no difference to the value of his goodwill. The bill did not deal with the goodwill of the tenant but with the pecuniary advantage which the landlord got at the end of the tenancy by the fact that a particular trade or business had been carried on in the house in question. He did not think that the fact that he had carried on the trade of a lawyer or a doctor in the trade of a doctor in a particular house was really going to bring in any more payment or reward during legal action to that house after the law was over another doctor or lawyer took it. Therefore the landlord would not get very much advantage from the fact that the business of a lawyer or doctor or a sculptor had been carried on in the premises in question. To go into all the question as to what the landlord had received in return on the fact that a lawyer doctor or sculptor had carried on his profession in the particular premises would complicate the bill very much and would make it very much more difficult. There was more to be said for the proposition in the amendment with regard to improvement. A doctor or a dentist in the East End might want to put up a garage or a paved driveway in the East End of London might think it necessary to enlarge his surgery. Either would be just as much an improvement as a tradesman's desired to enlarge his shop front and so on. A representative of the Government he did not propose to take part in the discussion on the amendment but he would say whether Sir P. Lee would accept a suggestion from him or think out perhaps to give a suggestion to give professional men the same part in the discussion as all that the bill would do for the amendment was to be pressed there was help to be a strong opinion of opinion in the Committee and the matter might ultimately have to go to the House to be

fought over again. The Committee might get out of the difficulty by confining the idea underlying the amendment to the earlier part of the bill and by adding, at the end of Subsection (2b) these words:

"Provided that so far as this part of this Act relates to improvements, premises used for carrying on a profession shall be deemed to be premises used for carrying on a trade or business."

That would go a long way to meet the views of the doctor, or even the sculptor, and would be a reasonable amendment. If it were generally accepted by members who opposed altogether any extension of the bill, and by those who wanted to extend it further, he thought it would certainly be accepted by the medical profession, and that the House of Commons would say that the Committee had come to a wise and sensible decision in the matter.

Sir G. Hohlir said that the amendment was inconsistent with the language of clauses of the bill which had already been passed. The language of Clause 4 in regard to the goodwill of a trade or business was quite inapplicable to the profession of a doctor or surgeon, or solicitor or barrister. The amendment sought to extend the bill to every private residence. If the amendment were accepted the gravest difficulties would arise. A landlord would be called on to pay goodwill to a doctor, but what would be the value of that goodwill to him? The landlord would never know what he had to pay.

Sir R. Luce said that he could not admit that there was no goodwill in the case of the professional man. In certain circumstances there was goodwill arising out of the place itself, and quite apart from the goodwill of the doctor, which had been built up by his professional ability. A doctor might settle in a town and convert a house into a place which became well known as a doctor's house. In many cases those houses went on from generation to generation. After what the Home Secretary had said, he was prepared to leave the matter in his hands entirely. On the understanding that the Home Secretary would move the amendment he had indicated, he (Sir R. Luce) would withdraw his amendment.

Sir R. Luce's amendment was accordingly withdrawn. Sir W. Joynson-Hicks then moved the amendment which he had already outlined in his speech. He said that the wording might be a little awkward, and it might be necessary later to pull the clause together a little. At any rate the amendment brought to the surface a question within the scope of the bill. He regarded it as a fair compromise. He too felt that the Committee would be prepared to accept it as a whole, though he did not want to force it in any way. The Home Secretary's amendment was agreed to.

#### Home Office Vote.

The House of Commons discussed, on July 14th, the estimate of £57,647 for the Home Department in 1927-28. Mr. Rhys Davies, opening the debate for the Labour party, said that among 6,000,000 workpeople engaged in factories and workshops there were each year 1,000 fatal accidents and about 170,000 non-fatal accidents. These numbers were not declining. The public was apathetic although the "Safety First" propaganda had in some factories brought very good results. Factories were more numerous and diversified than ever, but this country had fewer factory inspectors than before the war. About 207 inspectors in Great Britain had to visit 290,000 factories, Germany had 642 inspectors for 335,000 establishments. Enlightened employers already had medical staffs in their factories, and the safeguards should be brought up to the position of the best. Mr. Davies asked what methods were adopted to enforce the new regulations as to the use of white lead paint and to what extent wet rubbing down was now used. He declared that miners' myasthenia was increasing, and asked whether the arrangement made in 1924 for employing affected miners above ground was being observed. He desired to know whether there were means of applying the Workmen's Compensation Act to cases of steel smelters' catarrh which developed after men left the steelworks for other employment.

Mr. Tinker drew attention to the new Order under the Workmen's Compensation Act regarding "miners' bent knee" and "miners' bent elbow." He complained that by introducing the word "acute" a miner was compelled to carry on till totally incapacitated before a surgeon could grant a certificate.

Mr. Hilton contested Mr. Rhys Davies's suggestion that every large mill should have a medical staff. Every large town had an up-to-date medical staff in the local infirmary in the centre of the industrial area. Medical men in these infirmaries took great interest in mechanical accidents and had a localized knowledge.

Mr. Robinson asked what was being done by the Committee inquiring into dangers to health caused by dust and fibres, and suggested that next winter inspectors should pay more attention to cold rooms in factories.

Dr. Vernon Davies said that many thought a retrograde step had been taken when, to save £7,000 a year, the inspection of accidents was taken away from the certifying surgeons who previously had to go to the mill and see the machine where the accident happened. Now all that the certifying surgeon had to do was to go to the office and certify, and he practically never went into the mill, where under the old system he could draw attention to defects. The medical man's knowledge in co-operation with that of the medical inspector could be a great help, and he asked the Home Secretary to consider continuing again the inspection of accidents to the certifying surgeon.

Mr. Compton asked why cattle ringworm had not been scheduled under the Workmen's Compensation Act. Dermatitis among French polishers and lithographic workers also required the consideration of the Home Secretary.

Mr. Paling hoped the Home Secretary would make inquiries

into the possibility of scheduling silicosis in coal mines, a step which the Miners' Federation had requested for years. Stone drilling machines, which had lately been introduced in coal mines, gave off fine dust, and in the opinion of doctors men working with them were as liable to contract silicosis as were men in silica mines. He suggested that boys should be examined to see whether a tendency existed to myasthenia and excluded from the pits if it did. Did not the Home Secretary think sufficient evidence had accumulated to justify another committee of inquiry into myasthenia?

Sir William Joynson-Hicks, replying to points raised, said that compensation claims for such diseases as steel smelters' catarrh must at present be made within a year of termination of the employment which produced the disease. To extend this period would require an Act of Parliament. Although the number of factory inspectors had been reduced since 1913 from 222 to 205, the number of visits to factories had gone up. There had been fewer visits to workshops, and he admitted there was a case for more factory inspectors. Undoubtedly many thousands of works were not inspected each year, but the Home Office was limited by the Government's strenuous effort for economy. He was asking the present staff of factory inspectors to work harder, and they were responding gallantly. No evidence had been put before him that cattle ringworm in mankind would normally prevent a man carrying out his work. Whether he would be endangering the health of others by working was an entirely different point. The Ministry of Health was undertaking a special investigation into this disease, and he must wait the result before saying whether the disease would be scheduled. Miners' myasthenia caused the Home Office anxiety. In 1908 there were 386 new cases and 74 old cases, in 1924 3,445 new and 7,890 old. The Medical Research Council in 1923 made recommendations, including one for altering the terms under which the disease had been scheduled. A scheme had been drawn up by the Home Office giving effect to these recommendations, but the Miners' Federation had not yet stated its views on it. With regard to miners' bent knee and bent elbow, the point he had to consider was how far bursitis without inflammation incapacitated a man. The Medical Research Council had found that chronic enlargement of the bursa in front of the knee or elbow did not cause incapacity. If members, or the Miners' Federation, would bring medical evidence that a bursitis not associated with acute inflammation disabled the worker he would reconsider the decision.

Dr. Vernon Davies, intervening, asked for a definition of "acute" in bursitis. Sir William Joynson-Hicks quoted the Medical Research Council's declaration that "The certifying surgeon must always satisfy himself that the condition is an acute inflammation arising out of the workman's employment and of sufficient severity to cause loss of earning power."

Dr. Davies said that under that definition a man would have to be incapacitated from work for many days before the certifying surgeon could give a certificate. The Home Secretary offered to consider any medical evidence which Dr. Davies could give and to make any further inquiry necessary to satisfy the Miners' Federation. Though silicosis was not scheduled, compensation could be provided for it under the Workmen's Compensation (Silicosis) Acts if in any industry or group of industries there should be a scheme for provision of compensation. He had made a scheme for the refractories industries (granite musing, and gamster and silica brickworks, and quaries), and another scheme for the metal grinding industry (the grinding of cutlery and edged tools, machinery, etc.). The former scheme was working satisfactorily, the latter had just come into force and was not altogether popular, though employers had entered wholeheartedly into the working of the schemes. The Home Office and the Mines Department had conducted a medical inquiry into silicosis in coal mines and had examined men by x-rays. Tests and information had shown distinct evidence of silicosis in the lungs of these men. Thirteen men were found affected in one mine or group of mines, and in two or three cases very serious fibroid conditions were found by radiographic examination. Yet the owners of the coal mine, with whom he had conferred on the previous day, had denied that there was any silica in the mine. He was satisfied that the disease existed, and he had arranged that the Mining Association representatives should interview the medical advisers of the Mines Department, who had arranged for the examination of the affected men by doctors of the highest eminence. If the Mining Association was not convinced he must set up an inquiry, and, if then satisfied, would make an Order for the mining industry. He had had a large number of mines examined by an independent medical expert from South Africa. He declined to discuss lead paint again, there had not been time to find out how far the wet process was really being carried on.

The Vote was agreed to as was a subsequent vote of £503,901 for prisons in England and Wales.

#### Bills Advanced

On July 15th the House of Commons read the Poor Law Bill and the Diseases of Animals Bill a third time, and the Destructive Insects and Pests Bill a second time. The first is a consolidating bill. The second deals with the testing of imported cattle for disease with the destruction of infected cattle in this country, and with compensation for such destruction. The third provides for the destruction of infected crops. On the Diseases of Animals Bill Mr. A. V. Alexander said that milk tests showed a real danger from tuberculosis in our herds. Dr. Nathan Raw had said that he had over 2,200 patients whose tuberculosis was caused by infected milk and that 15 per cent of all milk supplied contained living tubercle germs. The Chairman said that this was irrelevant to the bill. Mr. Guinness said that between September 1st, 1925 and March 31st, 1927 owing to notification of tuberculosis on farmers' premises or to the tracing back of

tuberculosis milk premises were inspected housing 1,051,000 cattle. A seventh or an eighth of the cattle in the country. Of these 792,000 were cows and heifers, among whom 21,871 or 2.7 per cent were suffering from the forms of tuberculosis which brought them within the Tuberculosis Order—tuberculosis emaciation, chronic cough, and tuberculosis of the udder. The last by far the most serious danger only occurred in 0.5 per cent. The figures quoted by Mr. Alexander were terrifying but unfordoned.

In the House of Lords on July 18th the Widowers and Maternity Homes Bill (Scotland), and the Medical and Dentists Act Amendment Bill were read a second time. The last is a measure which is to confirm and give effect to certain agreements between representatives of Great Britain, the Irish Free State, and Northern Ireland as to the registration and control of medical practitioners and dentists and to valid to certain acts done by the Dental Board.

#### Pensions Vote

On July 16th Colonel Stanley introduced estimates of £33,242,852 for the Ministry of Pensions in 1927-28. He said nearly every item was subject to uncontrollable factors. The Ministry could not tell how many pensioners or dependants were likely to die during the year. A bad winter might cause more sickness among pensioners and send them to hospital. The administrative cost of the medical services of the Ministry was estimated at £298,700. The Ministry was a king £2,507,500 for the benefit side—a decrease of 8 per cent. Nearly half the cost of medical treatment was due to mental cases, the number of which remained fairly constant. The need for hospital treatment was diminishing but in a number of cases the ailments were liable to recur and for this reason hospital accommodation must be retained for some years. It was calculated that this year there would be an average of 1,000 in patients, medical as well as surgical, against 15,000 last year. This year 60,000 child dependants ceased to be eligible for allowances. Last year 4,500 widows remarried. In round figures there were now 1,000,000 pensioners and £50,000 dependants.

Major Cohen argued for the removal of the seven year limit on claims for pensions. The British Legion put this claim forward particularly for tuberculous cases and for troubles arising from gas poisoning. The limit had been fixed when no data were available.

Dr. Drummond Shiels said that Circular 20, on which the doctors had to work at present involved a difficult procedure and was not known to the ex-service man though doctors in hospitals sometimes told the men of their right to claim revision. Where men during the war suffered from malaria, bronchitis, or other diseases, ordinary ailments subsequently tended to take a more serious form and the men ran much greater risk of death. Why should there be discrimination when death was not wholly due to war disability? Some of the finest men in the army who carried on in spite of physical disabilities were penalized by a narrow hook keeping outlook. Other members also cited cases in which tuberculosis claimed to arise from war service, had not been pensioned. Mr. Naylor suggested that the Minister should advise doctors in hospitals when they had to certify the death of pensioners who had been under panel doctors, to consult first with those doctors. Sir Walter Greaves Lord said medical men were constantly finding that the origins of disease were much further back than they had thought. This was so in regard to neurasthenia. When that malady came on after a long period it was worse from the point of view of disablement. There were grounds for reopening a great number of these cases.

Major Tryon said Dr. Shiels was wrong in suggesting that changes made from time to time in warrants had been to the disadvantage of the pensioners.

The debate was adjourned.

#### Pollution of Rivers

In the House of Lords on July 18th Lord Biddam of Fleet opened a debate on pollution of rivers. He said that last February a deputation waited on the Lord President of the Council and urged that a central authority should be established to control inland water, and that local river boards should be created in support of that central authority. It urged also the necessity for scientific research to solve the innumerable problems attendant on the abatement of pollution. Something more was required than research. The Government ought to take action. The Earl of Balfour said the Government had appointed an Advisory Committee representing the Ministry of Health and the Fishery Board. The chairman would be Sir Horace Munro. The Committee would advise on new legislation on the setting up of new river boards and on inducing local bodies to co-operate with each other. A Committee now at work composed of men of science would carry on research into the pollution of rivers.

#### Research in East Africa

During the discussion of the Colonial Office Vote in the House of Commons Captain P. R. Henderson called attention to the research into leprosy in Uganda. It did not involve a large sum of money owing to the advance of medical knowledge and medical research which had made it possible to attack the disease effectively. He hoped that the special commission which had been set up to inquire into the federation of East Africa would be asked to direct its attention to the possible co-operation of East and West Africa in all the forms of research relating to the leprosy fly.

Mr. Amery in reply said that perhaps the greatest problem of all in East Africa was that of research. The problem of the leprosy fly was being coped with in conjunction with the League of Nations and it was hoped to carry the matter further in co-operation

with the Governments concerned. These problems including that of research into leprosy in Uganda concerned the whole of East Africa and that was one of the reasons why administrative unity was desirable.

#### Lead Paint (Protection Against Poisoning) Act 1926

In the House of Commons on July 13th Mr. Harnett asked leave to introduce a bill to remove the prohibition contained in the Lead Paint (Protection Against Poisoning) Act 1926 against the employment of women in painting buildings with lead paint. He said the bill would place women on exactly the same footing as men by allowing them to engage in the industry under the regulations laid down in the Act of 1926. Mr. S. Balfour opposed the bill. He said that the regulations were not satisfactory but it was preferred to go on being poisoned that was no reason why women should not be allowed to be poisoned. Leave to introduce the bill was refused without a division.

**Medical Adviser to the Mines Department**—On July 19th Colonel Lane Fox informed Mr. Lunn that the latest date for receiving applications for the appointment of the new medical adviser to the Mines Department was July 31st. After that the qualifications of the applicants must be carefully considered. The appointment could not be made for some time but would be announced as soon as possible.

**Lunacy Administration in the Sudan**—Mr. G. Locker Lampson told Mr. Pellicci Lawrence on July 19th that there were no regular lunatic asylums in the Sudan. Mild cases of insanity in Europeans were dealt with in the hospital. Violent or dangerous cases were sent to Cairo as soon as possible being directed to an institution on arrival. Cases of insanity among the Sudanese were always when possible sent to their homes, recourse being had to hospitals only on special accommodation was available locally, only in violent or dangerous cases.

#### Notes in Brief

No cases were now outstanding in which approved societies had failed to submit the books for audit.

Earl Winterton on July 18th stated that the Government of India had decided that an inquiry into the opium traffic in India was unnecessary.

Sir Kingsley Wood stated in reply to a question on July 18th that plague infected rats had been found in the *Flutard* which brought a cargo of grain to the Victoria Dock, London. Measures taken by the port sanitary authority included the mooring of the vessel in the middle of the dock and its fumigation for the destruction of the rat. The unloading of the vessel was later completed under the supervision of the officers of the port sanitary authority.

## Obituary

### SIR EDMOND SINCLAIR STEVENSON, M.D., F.R.C.S. ED.

Late President of the Medical Council, Cape Colony, and Honorary Vice-President, British Medical Association.

We have already recorded with deep regret the death of Sir Edmond Sinclair Stevenson at the age of 76, at his residence in Rondebosch, near Cape Town.

Sir Edmond Stevenson received his early education in Geneva, where he was born. He later studied medicine at the Sorbonne in Paris, but on the outbreak of the Franco-Prussian war he joined the French ambulance. He then resumed his medical studies and worked in Edinburgh, St. Thomas's Hospital, and King's College, London, obtaining in 1873 the diplomas M.P.C.S. Eng. and L.R.C.P. Ed. In the following year he became F.R.C.S. Ed. and in 1894 he graduated M.D. Brux. with honours. He went out to South Africa in 1873 and commenced practice at Philadelphia, in the Malmesbury district, but soon afterwards removed to Pondebosc. In 1892 he was nominated a member of the Colonial Medical Council, of which he was elected president in 1897, from 1900 to 1909. He represented the medical profession on the Council in spite of impaired health he volunteered for military service at the outbreak of the late war and was placed in charge of a hospital in South Africa, with the rank of lieutenant-colonel. In 1916 he was gazetted lieutenant-colonel, S.A.M.C., and was attached to the Alexandra Hospital.

He took a prominent part in the foundation of the Cape Branch of the British Medical Association in 1893, and was its president in that year and also in 1901. He presided over the South African Medical Congresses of 1894 and 1900.

In addition to conducting a large general practice, his patients including such well-known men as Cecil Rhodes, Sir Gordon Sprigg, and Sir William Cameron, he took special interest in surgery and gynaecology.

Museum

It was decided that the Museum should be closed during August as well as during September, and for such part of July as may be found necessary for the purpose of redecorating. The President

reported that steps were being taken to transfer the Strangewaters collection of specimens illustrating osteoarthritis from Cambridge to the College.

### Paying Patients in Hospitals

Mr. McAdam Peckles was appointed to give evidence before a special committee appointed by the Prince of Wales "to inquire and report to King Edward a Hospital Unit for London upon the question of hospital accommodation in London for persons prepared to pay more than ordinary voluntary hospital patients, and to report the conclusions at which they may arrive."

### Endowment for Annual Dinner

An offer from Mr Backston Browne to present to the College a sum of £500 to provide an annual dinner to be given on the College premises to Members Fellows and others, was accepted with cordial thanks.

## Le tiers

Professors and lecturers were elected for the coming year. The following is a list with the subjects in parenthesis:

**Hunterian Preceptors**—F M Atkinson (The pathology, diagnosis and treatment of abscess of the brain) Sir Arthur Keith (Six lectures on directed growth) J S Huxley (The surgery of the posterior fossa of the skull and the conus) S H Sheldon (An endo-cranial craniotomy) H S Montar (Recent advances in cerebral surgery) G Grey Turner (The treatment of congenital defects of the bladder and urethra by implantation of the ureters into the bowel) W E W Wardill (Cleft palate with observations on the causes of defective speech and their remedy)

Observations on the causes of defective speech and their remedy; A. Abrams (The physiology of violent exertion in relation to overstrain); A. Fleming (Lysozyme a bacteriolytic ferment normally present in tissues and secretions); L. O. Mann (The comparative embryology of the vertebrate eye).

periteneurization and carcinoma of the stomach) C E Shattock (Pathological specimens in the Museum) C P Wakeler (Surgical diseases of the salivary glands)

*Arno t Demonstratorship*—Six Arthur Keith (Six demonstrations on the contents of the M. eum)

## ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

A QUARTERLY meeting of the Royal College of Physicians of Edinburgh was held on Tuesday, July 12th, the President, Dr G M Robertson in the chair.

### *Fellowship*

Dr Alfred Irving Shepherd Watson (Carlisle) and Dr Walter Duncanson Chambers (Perth) were introduced and took their seats as Fellows of the College. Dr Robert Victor Morrison (Rangoon), Dr William Macrae Taylor (Edinburgh), Dr Douglas James Ackworth Kerr (Edinburgh), Dr William Alister Alexander (Edinburgh) and Dr Thomas Robert Fushiton Todd (Edinburgh) were elected Fellows of the College.

### Congratulations

On behalf of the College Sir Norman Walker congratulated Dr George M Robertson and Sir Robert Philip on receiving the honorary fellowship of the Royal College of Surgeons of Edinburgh which had recently been conferred upon them.

## Oil &amp; Business

On the motion by Sir Robert Philip the annual report as Curator of the Laboratory was approved.

It was intimated that Dr George M Robertson had been appointed a Trustee of the College

## Medical News.

THE combined meeting of the Section of Neurology of the Royal Society of Medicine and the American Neurological Association, of which we gave full particulars on June 25th (p. 1155) will be opened on the evening of Monday next, July 25th by a reception at the Royal Society of Medicine and the guests will be received by Sir James Berry, president of the society, and Lady Berry. At 9.30 p.m. Sir James Purves Stewart, president of the section will give an address on "Mount Athos, a survival of the Middle Ages." Tuesday will be given up to the reading of short papers, and on Wednesday morning there will be a discussion on the cerebellum. On Thursday there is to be a discussion on sensory disorders in organic disease of the nervous system and at 5 p.m. the Huxtings Jackson lecture will be delivered by Dr Charles L. Dana. During the afternoon demonstrations on pathological subjects will be given, and there will be a dinner in the evening.

CIVIL list pensions of £75 have been awarded to Dr. George Alexander Pirie, in recognition of his self sacrificing and devoted services to the application of radiology to medicine and to the widow of Dr. G. Inman, in recognition of his contributions to the pathology of tuberculous. Mr G. W. Williams, F.R.C.S., has received a pension of £50 in recognition of his self sacrificing and devoted services in the routine application of x rays to the treatment of disease.

In view of the incidence of dermatitis among persons handling flour and sugar the Home Secretary, after consultation with the National Association of Biscuit Manufacturers,

facturers, has issued a draft order. The main reason for this is the provision and maintenance of suitable washing facilities, but in addition the occupier is required to arrange for a systematic inspection of the hands and forearms of all persons employed in the processes in order to detect early signs of dermatitis. The inspection is to be carried out by a responsible person and to be made once a week. If a person who is in contact with sugar or a mixture of sugar and other ingredients shows a tendency to develop, or is known to be susceptible to dermatitis, he is, if practicable to be transferred to other work. An official cautionary notice for posting in places where such work is carried on has also been prepared. Objections may be lodged with the Home Secretary within thirty days.

THE Fellowship of Medicine announces that Mr A. Caddy will give a lecture demonstration on glaucoma at the Royal Westminster Ophthalmic Hospital on July 26th at 5 p.m. free to medical practitioners. There will be an afternoon course in diseases of infants at the Infants Hospital under the direction of Dr Eric Pritchard from August 6th to 21st, with special visits to the Model Pasteurizing Plant Willesden, the Home for Blind Babies, Chorley Wood and the V.D. Centre, Charles Inn. A course in medicine surgery and the specialties will be held at Queen Mary's Hospital, Stratford, from August 29th to September 10th during both mornings and afternoons. The Fellowship of Medicine provides a general course of instruction at the associated hospitals for which a comprehensive ticket is issued for any period from one week to one year, the holder is free to make up his own time table from headings in the programme supplied. Copies of all syllabuses are obtainable from the Secretary of the Fellowship, 1, Wimpole Street, W. 1.

THE St Bartholomew's school students' dinner will be held on Monday, October 3rd, at 7.30 p.m., in the great hall of the hospital, with Dr H Morley Fletcher in the chair. The honorary secretaries are Sir C Gordon Watson and Mr P M Vicl.

DR P G GAPPEIT on leaving Earl Shilton Loocestershr, for Henfield, Sussex, was presented with a hall clock an illuminated address, and a book containing the names of subscribers.

THE Hanbury Memorial Medal for original re-search in the chemistry and natural history of drugs has been awarded to F. A. Henrv, D Sc, direct-r of the Wellcome Chemical Research Laboratories

BY an Order in Council the powers of the University of London Commissioners have been continued to the end of 1928

THE King has been pleased to appoint Sir James Crawford Maxwell, M D, K B E, C M G, to be Governor and Commander in Chief of Northern Rhodesia.

FIELD MARSHAL THE DUKE OF CONNAUGHT has appointed Colonel Sir John Atlin, KCMG, MB, and Vairans Antonius Johnston, D. Laris, Triffin Esq., O.B.E., M.D. to be Physicians in Ordinary to His Royal Highness in the room of Colonel Sir Edward Scot Worthington, K.C.V.O., C.B., CMG, C.I.E., M.D. resigned.

THE Exchange Secretary of the National Union of Students (3, Eadsleigh Gardens London W C 1) is prepared to recommend young university men or women from France or Germany who would be suitable guests of English families during the summer vacation.

At the recent examination for the diploma in librarianship of the University of London thirty passed but 0000 of them will be eligible to receive the diploma until they have furnished the necessary certificate of employment in an approved library

DR R KAGBOWN, medical officer of health, Bermuda, where artificial light therapy has been extensively carried out under the public health department has been appointed medical editor of the *British Journal of Actinotherapy*.

The fifty second annual report of the Mission to Lepers contains a short summary by Dr. R. G. Cochrane of the improvement in the therapeutic outlook in leprosy which has followed the introduction of the ethyl esters of chaulmoogra oil. The number of lepers now being treated directly or indirectly by the Mission exceeds 9,000. Additions were made during 1925 to its institutions in Bihar, Bengal, the Punjab, the Central Provinces, Madras and China; the civil disturbances in the last named country have not, it is stated, interfered seriously with the work of the Mission. New buildings of various kinds have also been constructed in Korea and Formosa, and similar extension is contemplated in Kenya and Uganda. The report, which is freely illustrated and contains details of the work in several places, is published at £d and together with the quarterly magazine of the Mission, *Without the Camp*, for which the subscription is a year may be obtained from the secretary of the Mission, 33, Henrietta Street, W.C.2.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W C 1**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W C 1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSLUM 9561, 9562, 9563, and 9564** (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are  
LDITOR of the BRITISH MEDICAL JOURNAL, *Atiology Westcent, London*

FINANCIAL SECRETARY AND BUSINESS MANAGER  
(Advertisements, etc.), *Articulate Westcent London*

MEDICAL SECRETARY *Mediscera Westcent, London*

The address of the Irish Office of the British Medical Association is 16 South Frederick Street, Dublin (telegrams *Bacillus, Dublin*), telephone 4737 (Dublin), and of the Scottish Office, 6, Drumshigh Gardens Edinburgh (telegrams *Associate, Edinburgh*), telephone 4361 (Central).

### QUERIES AND ANSWERS

#### TREATMENT OF THIRADWORMS

DR J FINCH HAINES (West Hampstead) writes in reply to "India": I have found the following treatment for threadworms invariably successful, if regularly persevered in—5 grains of sulphur three times a day, and a teaspoonful of liquid paraffin nightly.

#### OMENTAL TRAPS

"M B, CH B" writes: I have a mind under my care who received an abdominal injury several months ago and still has pain of a character difficult to explain taking the present findings into consideration. I should be grateful for references to cases of a similar kind and then after symptoms. The history is briefly as follows: The man was working, along with his colleague in the pit. The latter was swinging a 16 lb hammer, in the act of hoving coal when the head flew off. My patient was struck in the abdomen, in the gall bladder region, and became unconscious for a time. His symptoms now are occasional pain on movement exactly over the place of injury and there is slight rigidity of the rectus muscle in that region. X-ray photographs show no abnormality, stomach and duodenum are absolutely normal and the pain is not of muscular origin.

#### INCOME TAX

##### Assistant's Remuneration

"HUMBRE" is in partnership with his brother, and they have employed an assistant as from March 3rd who will probably become a partner as from September 1st. The firm's liability for 1927-28 is based on their earnings for the year in April 5th, 1927, which were reduced by the assistant's salary etc. for one month, whereas that cost will affect five months of 1927-28.

\* \* The firm have no remedy. It is a fact that their income tax liability for 1927-28 is likely to exceed their earnings for that year, on the other hand, in 1928-29 their three sevenths shares of the partnership earnings of that year (including those of the new partner) are likely to exceed their liability, based, as it will be, on the earnings of 1927-28, after deducting the assistant's cost up to the date as from which he becomes a partner. In the long run there should be no appreciable injustice.

#### Allowable Expenses

"H F B" inquires whether he can deduct as professional expenses (1) salary and cost of board of maid, (2) also of housekeeper, (3) fitting of electric light and power in surgery, (4) subscriptions to British Medical Association and Medical Defence Union, and (5) contributions to fund for accommodating special cases at Annual Meeting of British Medical Association, and subscriptions to Epsom College and medical benefit etc.

\* \* (1) and (2) Yes, to the extent or in the proportion to which these employees devote their time to looking after the professional, as distinct from the domestic side of the establishment—presumably very small as regards the housekeeper. (3) No, this represents capital outlay, though some allowance may be due if the old (? gas) fittings required replacement. (4) Yes. (5) On the whole, we think these deductions would be inadmissible, as representing private or semi-charitable expenditure.

#### Three Years' Average

"W B K" was employed by the Ministry of Pensions but that work practically ceased in 1924, and in the year 1924-25 his professional work resulted in a loss. He has now claimed to retain the advantage of the three years' average for 1927-28, and the local inspector refuses to admit that claim.

\* \* The earnings from the Ministry of Pensions were assessable as those of an employment, and must be severed from consideration of the proper basis of assessment of the general professional earnings, which appear to have commenced in 1924-25. Section 29 of the Finance Act, 1925, which deals with the modification of the change to the previous year's basis of assessment, applies to persons assessable "for the year 1925-27 upon an average of a period of three years or more." If

"W B K" was not in general practice in 1923-24 to an appreciable extent, then his general assessment for 1925-27 would be on the average of 1924-25 and 1925-26—that is, of two years only, and he is not within the Section. He might find out from the inspector whether this is in substance the ground of refusal, and if it is, then apply for a revision of the assessments for each of the three years 1924-25, 1925-26, and 1926-27, to the amount of the actual profits of the year under the provisions of the 1842 Income Tax Act—if that course is worth pursuing, having regard to the amounts of the respective years' earnings and the averages applied.

#### Motor Car Expenses

"L M" bought a car in 1924 for £141. He sold it in 1926 for £50, buying another car for £269. He applied for depreciation allowance last year, but did not receive it until he explained the above transaction when he was allowed 15 per cent on £229=£34.

\* \* Seeing that the car was not purchased until 1926, depreciation on that car was not claimable in the normal course until 1927-28, and in our opinion the 15 per cent should have been applied to the full value of £269. As regards the old car, the net cost of replacement, excluding improvement, was apparently £141-£50=£91, and an obsolescence allowance should in fairness be given, though certain technical objections can be raised. That allowance would take the form of including £91 as a professional expense of the year 1926.

### LETTERS, NOTES, ETC.

#### A DISCLAIMER

DR EUGEN STEINACH, the University of Vienna, asks us to state that he has no connexion with the Dr. Frederick Heyman Institute. He has been informed that such a connexion is implied in an advertisement which appeared in several London newspapers, and Professor Steinach wishes to protest against the use of his name in this connexion.

#### THE TESTING OF DISINFECTANTS

MR J F AINSLIE WILKINSON, F.R.C.S. (London, E C 4), writes with reference to the letter under this heading in our issue of July 9th (p. 79) as follows:

"The original note which supplied material for the test was published by me in the *Practitioner* (vol. LXIX, No. 413, 1902). The suggestions put forward in that note were elaborated by Dr. Samuel Rideal and myself in the form of a paper which we read at the Bradford Congress of the Royal Sanitary Institute in 1903. For a number of years the method as described in that paper was adopted officially by Government departments here and in the Colonies with slight modifications (such as the substitution of a standard sterilized saline solution for distilled water in the preparation of all dilutions of the postulant, while the disinfectant under test was required for use at sea—or sterilized urine when employed in latrine work—but the actual technique remained the same). After the experience of a number of years Dr. Rideal and I decided to embody in the test various improvements which had been suggested by us from time to time, and thus we did in the brochure published in our joint names by H. K. Lewis and Co. in 1921."

#### THE LATE MR STANFORD MORTON

In last week's issue of the **JOURNAL** (p. 117) occurred a regrettable slip on the part of the printer. In the sentence introducing Lieut.-Colonel A. E. J. Lister's interesting note on the operative skill of the late Mr. Stanford Morton the name appears twice as "Mr. Stanmore Morton." The name was given correctly later on, and it is hoped that his many friends and admirers will excuse the lapse.

#### VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments in hospitals will be found at pages 35, 38 and 39 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 36 and 37.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 56.

## Remarks

ON

## FRACTURES OF THE FIRST CERVICAL VERTEBRA \*

BY

C. OTFRIJ JEFFERSON, M.S. F.P.C.S.,

HONORARY SURGEON, SALFORD POLICE HOSPITAL, LANCASHIRE  
NEUROLOGICAL SURGEON, 3 CHESTER ROAD, LIVERPOOL

In a previous paper I described at some length the pathological anatomy, mechanism, and symptomatology of fracture of the atlas vertebra. Having now three more recent examples of this injury to add to the four published then I may take this opportunity of bringing the history of the subject up to date, and of making such amplifications or amendment as further experience seems to demand. The whole question of atlas fracture is in reality undeniably bound up with the matter of injuries to the occipital-atlanto-axial component of the vertebral column, both bones and ligaments. I shall be compelled by the necessary limits of space to confine my observations strictly to the atlas, and will have to reserve for another occasion the many fields through which a fascinating subject might well tempt us to wander. So much that is dramatic but untrue so much that is interesting yet founded on legend obscures the facts in this corner of surgery that it is impossible to take up the thread of the narrative in modern times. A complete survey of the history of the various lesions is required before we can go forward along a sure path. As regards atlantal injury I have previously sketched in the necessary background, but will once more outline the chief features after describing the new cases.

## MATERIAL

In 1920 I described four examples of atlas fracture—two clinical examples and two museum specimens—and collected forty-two other cases from the literature. I have omitted cases of gunshot injury in the present communication. The total material personal and otherwise now amounts to sixty-five cases. I am indebted to Dr. Arnison and Dr. Forbes for two of them (see Tables I and II).

## CASE I—Fracture of the Posterior Arch of the Atlas

A man aged 57 was sent to see me in 1920 some five months after an accident which had left his neck very painful and stiff. He was unable to describe the exact facts, but was drawing water in a slightly stooping position when a telegraph pole blown over by the wind struck him on the back of the head. The scalp was not cut, there was no bleeding from the nose, mouth, or ears. He was stunned for a short time and when he became conscious

FIG 1—Case I. Fracture of the posterior arch of the atlas in two places.

he had great pain in the neck in the shoulders and in the arms as far as his elbows. He had been in bed for eight weeks. His arms had not been till weak so that he could not raise them high above his head or get his hands easily into his trousers pocket. He had had no difficulty in walking. The outstanding feature of the case had been the pain in the occipital region of the scalp and although this was improving it was still very troublesome—so much so indeed that he was in the habit of placing a wet handkerchief on his head to allay the burning pain. On examination I found that the head was very stiffly held and that movements of rotation and of nodding were practically abolished. There was an area of calp analgesia on both sides in the distribution of the great occipital nerves greater in extent on the right than on the left. He could abduct the arms fairly well but the right deltoid, biceps and triceps were flabby without being definitely palsied. There was a small patch of anaesthesia corresponding to the skin areas of root C5 on both arms. There was no sign of interruption of the pyramidal pathway to the legs on either side. A radiogram disclosed fracture of the posterior arch of the atlas. Seen again a month later he was making low progress but the occipital neuralgia was still severe.

In this case the atlas fracture appears to have been complicated by a slight cord hemorrhage at the level of C5 but it must have been extremely minute. Alternatively a peripheral injury to the issuing roots of this segment may have been occasioned in some manner.

## CASE II—Fracture of the Posterior Arch of the Atlas and of the Anterior Arch of the Axis

A woman 67 years of age was admitted to the Salford Police Hospital on February 22nd 1925 with a history that the previous day he had fallen down stairs in her home and she thought twisted her neck with a very painful injury. It was almost impossible for her to find any comfort in any position in bed. There was no tenderness or abnormality in any arm or leg. I found on questioning her that the fall had taken place in her kitchen and ran across the hall. That the dividing wall was only a few feet from the foot of the stairs. In falling she had struck the top of her head against the wall or on the passage. There was a small cut one inch inside the hairy scalp about the site of the coronal suture near the midline so that the force striking the top of the head might also have extended it. Flexion and extension of the head were impossible and her power of rotation was abolished. An x-ray photograph revealed a bilateral fracture of the posterior arch of the atlas and a fracture of the dens process and posterior arch of the axis. The occipital-atlanto-axial component of the vertebral column was reduced to a state of complete immobilization and she had neck pain and could not move her head. She remained in hospital for a month and was discharged to her home. After six months she began to have the pain removed. This was done and she was promptly discharged. I have recently re-examined the patient. Movement of the neck are a little restricted in most directions but she declares herself to be perfectly well. A radiogram of the atlas and axis showed in perfect form.

FIG 2—Case II. Fracture of the posterior arch of the atlas in two places and of the dens process of the axis.

## CASE III—Fracture of the Posterior Arch of the Atlas

A man 34 years of age was admitted to the Salford Police Hospital on October 20th 1925 under the care of my colleague Mr. Ollerenshaw who was knowing my interest in the case. Later kindly transferred to the case of mine. It appeared that a bag of starch weighing 100 lb had slipped from a shelf at a dock warehouse and had fallen from a height of five to six feet on to the upper and back part of the patient's head, knocking him down and temporarily stunning him. He had the usual severe pain in the neck with neuralgic pain streaming up on to the back part of the scalp. There were no signs of cord or root injury. The neck seemed rather swollen and was extremely tender to touch behind. I revealed a fracture of the posterior arch of the atlas on the left side with a negligible fracture of the spinous process of C5. The odontoid process was intact there was no luxation of the head. The neck was immobilized between sandbags and after five weeks in hospital he was discharged with a leather collar. I have seen him from time to time during his recovery and he has done well. His neck is still a little stiff but this is probably partly due to apprehension as he knows he has had a broken neck. He has complained of tingling along the inner sides of the arms into the inner two fingers on both sides as if he had known of his tumb bones. He had a similar tingling in his calves especially when he turned his head far to the right or left. There is an area of hypoaesthesia needled over a part of the calp area supplied by the great occipital nerve. In a telegram taken on May 1927 the atlas still shows a discrepancy of the left arch but there was unusual separation of the fragment in this case.

FIG 3—Fracture of the posterior arch of the atlas and of the spinous process of C5.

## SOME GENERAL CONSIDERATIONS

If we turn to the standard work we shall strengthen the impression which was probably implanted in our dissecting room days that injuries of the first cervical vertebra are on the one hand exceedingly rare, and on the other extremely fatal. Both of these ideas are wrong, although a degree of rarity cannot be denied to a condition of which only a few or very few cases appear to exist in the world's literature. The figures are probably misleading for it is strange that I should have seen so relatively high a percentage involved. The fact is that a number of cases are undiagnosed not because the injury is any especially difficult to discover, the true nature of the case, but because the belief in the fatal nature of the condition is so strong that the practitioner does not suspect such a lesion in his patient lives. The stiff and painful neck or atlantal injury is put down to a "sprained neck," and it is only when

the condition fails to resolve itself—and some cases get well fairly quickly—that the more wary send their patients for early examination.

It is easy to understand how this belief in the almost uniform fatality of atlantal injury has come about. There are in currency apocryphal tales of slight accident and of pranks leading to sudden death. Many such cases have undoubtedly occurred. The reader may turn to Greene Gracigno's case, for example, but he will find that, as a rule, in these cases the violence has been considerable, more considerable perhaps than the participants would willingly admit. The classical example of minimal violence leading to death is that of the child lifted up by the head and set down dead. As this refers to rupture of ligaments, and not to atlas injury, I shall not at present make a detailed reference to this case, of which many variations in folklore exist. The origin of this story goes back to France 150 years ago, and is not founded, so far as I can learn, on definite pathological observation. Much more convincing, however, than any fanciful tales were the older, well documented records of atlantal, odontoid, and arch fracture, which are chiefly concerned with fatalities. How else could the clinician of last century and earlier times confirm a diagnosis of fracture of the upper cervical vertebra except by necropsy? If there was cord damage, and often there is none, he was on sure ground, but even then there was no certainty as to the precise nature or even the exact site of the bony injury. Thus we find the earlier history of atlas fracture in essence a record of death, up to the introduction of radiography, since when a change has come over the picture. I find that of thirty-two cases reported since 1900, only six have died, so that one's impression at present is that atlas fracture, though fraught with the possibility of danger, is by no means always fatal. Indeed, when the posterior arch alone is broken—and this is the commonest type—there should be no particular anxiety. The real danger lies in the nature of the force which is required to bring about the lesion, for this may not stop at fracture of the atlas, but may go on to cause other injuries. In order that I may make this clear it will be necessary to speak of the mechanism of fracture, when we shall see that an injury of much the same type may produce now a fracture of the skull, now a fracture of the atlas, whilst a slight difference in the direction of the trauma causes the injury to fall into the cervical spine at a lower level. For the vast majority of cervical injuries are produced by forces applied to the head and not directly to the neck. This is a fundamental point, and it is essential that the fact should be realized in all its implications.

#### SITE OF INJURY WHEN FORCE IS APPLIED TO THE HEAD

If the wounding body is a hard unresilient material a fracture of the skull is naturally the most probable result, the skull being compressed between the spine at the occipital condyles and the injuring agent. Even so, a fracture of the spine may occur as well, and I suspect that these double injuries are more frequent than we think. I have seen one such only. Clinically the head injury quite overshadows all else, whilst at necropsy the pathologist is satisfied when he finds cranial lesions. In the monograph on fractures of the skull by Briquay and Laubie (Experience XIV) experiments are recorded in which the posterior arch of the atlas, as well as the skull, was broken by longitudinal compression of the head on the spine. If the injuring body is more elastic and yet heavy (as when a bale of cotton or sugar or starch falls on to the head, or as when a person falls from a height on to sand) the skull will escape and then the lesion may fall into the vertebral column at some point. Where? If the neck is violently flexed the injury will probably be found in the lower cervical vertebrae, at the point where the change in the mobility of the spine takes place (C5 or thereabouts). If, on the other hand, the head is erect and the force is transmitted along the spine vertically an injury to the relatively weak atlas may result, and thus for a special but simple reason. I have described in my previous paper the widening of the atlas ring which occurs by the resolution of the forces acting upon it, but a few words of

recapitulation are needed. The lateral masses of the atlas are triangular in coronal section with the wide bases outwards. The upper and lower articular facets look inwards and upwards and downwards, respectively. When the head is pressed down on to the vertebral column the atlas is squeezed between the occipital condyles above and the axis below, and, owing to the obliquity of its articular surfaces, the wedge-like lateral masses tend to slide outwards. (I have illustrated this diagrammatically elsewhere.) This tendency is resisted by the anterior and posterior arches which bind the lateral masses together, and also by the transverse ligament, which not only holds the odontoid in place, but acts as well as an internal brace for the lateral atlantal masses. This ligament is, contrary to general belief, exceedingly strong, and its rupture is one of the rarest of all accidents in healthy people. If the limits of bony cohesion are passed a tension fracture occurs, the atlas ring gives way.

FIG. 4.—Diagram made from a normal shrinkage. To illustrate the theory of atlantal squeeze.

It is usually the posterior arch, where it is weakened by the grooves for the vertebral arteries, that breaks. It is because the force is centrifugal, from the centre outwards, that paralysis is rare in simple atlas fracture, the fragments move in the safe direction, away from the cord. The force which has driven the head and the atlas down on to the axis may stop there, but should it go on further injuries may arise, especially if violent flexion is added. If the neck remains rigidly erect, with articulations locked, and the head alone be violently flexed, the odontoid process will probably be pulled off by the check ligaments (an "abaissement"). Alternatively, should the head and neck be flexed forwards as a whole the additional injury will fall on the spine in the lower cervical region. Examples of both of these happenings will be found in the literature (see Table II). Now what of direct injury? Can the atlas be broken by direct violence?

#### Direct Injury

Direct injury applied to the back of the neck may on rare occasions break the atlas. The bone is so deeply situated, and lies guarded by the overhanging of the occiput above and by the strong and longer spine of the axis below, that it needs a very accurately localized blow with a narrow heavy implement to miss these and strike exactly over the atlas. Fracture has been caused by this means, but not in any cases I have myself seen. In Hugues's case a woman was struck on the back of the neck with a stick and instantly killed. At necropsy the posterior atlantal arch was driven forwards and jammed inside the lateral masses. In Armstrong's case a man hit by a baseball bat in a somewhat similar fashion died of dislocation of the head from extensive ligamentous rupture. The atlas injury here was of minor importance. In Ridley's case the mechanism is not so clear, and, from the brief account of the case, it seems that the coincident fracture of the base of the skull was a more essential cause of death than the atlas injury. In the whole literature these together with the cases reported by Sierd and Roger, by Blanc, and by Scott—in all—represent the sum total of atlantal fracture by this direct mechanism. Gunshot wounds have been ruled out of the present series as they are of no particular interest.

On the whole the theory of transmitted force, of atlantal squeeze, is the one which fits the facts in the majority of the cases. The possibility that the anterior arch might be broken by the pressure of the odontoid process presents itself, and it may well be an accessory mechanism, if not the primary cause. Too much space would be required to discuss the matter in detail here.

#### Pathological Anatomy

An analysis of the cases in which the description of the fracture is sufficiently clear shows that fracture of the posterior arch is the most frequent type, sometimes on one

side only, sometimes on both so that the arch is mobilized. In spite of this little harm ensues as there is generally little or no displacement and the posterior arch may not be ruptured.

Anterior arch alone	8 cases
Posterior arch alone	23
Both arches	12
Isolated arch	7
Transverse process	3

The posterior arch is more often broken because it is weakened by the groove for the vertebral arteries. But in addition the long axis of the facet for the occipital condyles being placed diagonally may assist in tending to split the arch behind opening it like a tin.

#### Concomitant Injury

(a) In the recent literature is fracture of the odontoid process which has occurred at least sixteen times. Authors mention anterior and posterior luxation of the teeth in their reports but coming to realize that this cannot occur unless the odontoid process has happened—fracture of the odontoid or rupture of the transverse ligament. The former is more probable. This is a fracture rather than the atlantal fracture which has often been the result of death (see Table II).

(b) The vertebral artery may be ruptured. The region of the groove for this vessel on the posterior arch seems to be a favourite site for fracture and here the artery is bound down in close contact with the bone by a ligamentous slip passing over it. It is not uncommon to find this ligament ossified and it then shows clearly in x-ray films. If the ligament is only partly ossified it appears in x-ray films as a spicule and may be mistaken by the unwary for the relic of an old fracture. The elasticity of the vessel wall and the usual lack of displacement of the fragments accounts for the relative rarity of injury to this vessel.

(c) The great occipital nerve. As was first pointed out by Sicard and Poger this nerve may be injured, indeed ruptured in atlantal injury. Several examples will be found amongst the tabulated cases, including some of my own. Occipital neuralgia after injuries to the upper two cervical vertebrae is certainly very common and is a useful clinical help in drawing attention to the possibility of fracture having occurred in otherwise doubtful cases.

(d) Injury to the spinal cord or lower end of the medulla. For the reasons already detailed this complication does not happen often in pure atlantal injury. We have seen that the bone fragments tend to move away from the cord in the average case and that there is often little or no displacement or bone fragments. Thus in the whole series of uncomplicated atlas fracture twenty-one in number, the medulla was found injured by a bone fragment in only two (Betz and Bouillard). Myelitis probably traumatic accounted for two or three more. The presence of suppuration in Marshall's case is not commented on by the author. In the complicated cases the injury to the atlas often sinks into a subluxation position, and the cord injury is inflicted at the site of the complicating fracture. For example, when the odontoid is broken off there is a great tendency for the occipito-odontoid-atlantal component to be dislocated forward more or less backward and the cord is then much more likely to suffer. A normal external appearance of the cord may have misled some observers, as this is not inconsistent with the presence of a central hemorrhage and central pulsing sufficient to cause death.

#### SYMPTOM OF FRACTURE OF THE ATLAS

Pain and rigidity of the neck so that movements of the head are slowly and hardly performed, are the outstanding features. The patient in the first few days has the greatest difficulty in finding a comfortable position in bed and is constantly demanding a change in the arrange-

TABLE I.—Isolated Fractures of the Atlas (20 Cases)

Author	Nature of Accident	Clinical Signs of Cord or Nerve Injury	Anatomical Diagnosis	Result
1. Astley Cooper (Cline's case) 182	Severe fall injuring neck (5-year-old boy)	None	Boharcus of a broken arch	Died 12 months later (in current disease presumed) No mention of condition of cord at autopsy
2. Bouillard 189	Daske heavy with moisture fell from a height on upper and back part of head	Pain in neck. No paralysis at first but cramp developed. Complete paralysis before death.	Fracture of posterior arch of atlas right. Comminuted anterior arch fracture on to inferior articular face lateral mass left.	Lived 33 days
3. Marshall J 1875	Fell from second story window	Monoplegia right arm progressive to paraplegia both arms and right leg	Fracture right lateral mass on atlas	Died 9 days later infection of fracture with abscess of cord
4. Betz 1883	Fell on neck and shoulder	Progressive paralysis of arms and leg	Isolated fracture of posterior arch of atlas	Died 3 months later. Half-cm. piece of bone driven against medulla local hemorrhage in medulla
5. Hugue 1897	Healthy woman 'rueled' on back of neck with a stick	Instant death	Fracture posterior arch of atlas right and left through groove for vertebral artery. Arch driven in and impacted. Vertebral artery torn. Fracture left lateral mass on atlas	Instant death
6. Lindloff 1895	No available	No available	Fracture left lateral mass on atlas	Recovered
7. Holdin 190	Fell down stairs on to back of head	No cord signs. Severe occipital neuralgia	Isolated fracture of atlas	Recovered
8. Quercioni 1905	Fell from tree	No limb palsy. Dysphagia	Atlas broken into four pieces by mechanical fracture of both arches	Died 15 days later from pneumonia. No cord found in a hard at autopsy
9. Corner 1909	Poked on of chair with head flexed	No cord signs. Severe neuralgia great occipital nerve	Fracture of atlas	Recovered
10. Schneider 1911	Fell down stairs	Monoplegia right arm recovered	Fracture anterior arch of atlas	Recovered
11. Park 1913	No available	No available	Fracture anterior arch of atlas	Recovered. Care of atlas examined by Cline
12. Sicard and Roger 1915	Plate of paper dropped on to head from a height	No cord signs. Anashe is left great occipital nerve	Fracture posterior arch of atlas	Dislocated laterally. Pneumonia. No injury to cord. No occipital nerve involvement. Recovered
13. Sicard and Poger 1915	Fell 6 ft on to head	No cord signs. Anashe is left great occipital nerve	Fracture posterior arch of atlas left side	Recovered
14. Sicard and Roger 1916	Struck by a beam on left side of back of head and neck	No cord signs. Anashe is left great occipital nerve	Fracture posterior arch of atlas left side	Recovered
15. George 1919	No available	No clinical details	Fracture posterior arch of atlas two places	Presumed recovered
16. George (Butler's case) 1919	No available	No clinical details	Fracture posterior arch of atlas one place	Presumed recovered
17. Jefferson 1920	Aeroplane crash fall on to head	None	Fracture posterior arch of atlas two places	Recovered
18. Jefferson (Lang staff's case) 1920	Thrown from horse	Laceration brain stem	Fracture posterior arch of atlas two places	Delimbed. Recovered
19. Arnison (private communication) 1920	Man thrown from horse on to head	Pain rigidity of neck. No signs of cord injury and compression	Fracture posterior arch of atlas	Recovered. Still rigid to

TABLE II—Complicated Fractures of the Atlas (45 Cases)

Author	Nature of Accident	Clinical Signs of Cord or Nerve Injury	Anatomical Diagnosis	Result
1. Iell Charles 1824	Fell fifty feet on to shoulders	—	Fracture (2 posterior) arch and portion of body of atlas Odontoid process broken off	Instantaneous death presumably from medullary injury. Autopsy but no mention of condition of brain stem
2. Phillips 1837	Fell off hayrick on to occiput	None	Fracture posterior arch of atlas in two places Dislocation of remaining part forwards Odontoid process broken off	Died 47 weeks later of anasarca (nephritis) Fracture had done well
3. Spangenberg 1845	Fell off horse on to head	None	Fracture posterior arch of atlas Odontoid broken off	Died 15 months later Osteomyelitis of atlas and axis Cold normal
4. South 1847	Fell down stairs	Tetraplegia with hyperaesthesia in right half of the body	Atlas broken in two places Odontoid broken off Fracture 5th cervical vertebra	Died 5 days later Haematomyelia level of 5th cervical vertebra
5. Melcher 1848	Woman fell backwards down a ladder 7 ft	Violent pains in neck and occiput Weakness of lower limbs progressing slowly to total paralysis	Fracture anterior arch of atlas Odontoid process broken off	Died 4 days later
6. Melcher 1850	Fell off ladder	—	Posterior arch of atlas broken in two places Odontoid broken off Dislocation atlas on axis	Died instantaneously Brain stem compressed
7. Speyer 1851	Fell on head	Monoplegia right arm progressing in 2 to other limbs	Fracture both arches of atlas Odontoid broken off	Died 10 days later No loss injury to cord Blood extravasation over medulla
8. Gascoigne 1856	Hat jammed down on to head and pulled from side to side (in a horse play)	Head fell forwards, chin on breast Paralyzed	Fracture posterior arch of atlas and arches of 2 3 4 cervical vertebrae Partial luxation C 3 on 4	Died in 40 minutes
9. Uhde 1855	Man fell from tree on to occiput and back	Pain in the neck Palsy lower extremities later of upper also	Fracture posterior arch of atlas also of neural arch of axis Fracture C 6 7	Died 13 days later
10. Birkett 1859	Man fell down stairs intoxicated	Completely paralyzed below neck	Fracture posterior arch of atlas C 3 dislocated forwards on C 4	Died in 36 hours
11. Ridley 1859	Man knelt down by blow back of head came against curb stone	Pain in neck bleeding from ears General headache Deep furrow between atlas and occiput	Fracture posterior arch of atlas Dislocation of atlas forwards Fracture of occipital parietal and temporal bones	Died 3 days later in convulsions
12. Gayet 1870	Slipped on stairs and lost fall with a fall	Severe pain in neck Support of head with hand Palsy appeared four weeks later	Fracture lateral mass of atlas and of axis Fracture odontoid process	Died 5 to 6 weeks later
13. Hamilton 1872	Fell 140 ft on to vertex	Paraplegia below the nuchal level Arms normal	Fractures of both arches and right transverse process of atlas Odontoid unimpaired Fracture 6th cervical vertebra	Died 48 hours later Cord compressed at level of 6th cervical vertebra
14. Milnor 1874	Fell off roof neck probably flexed	—	Posterior arch of atlas fractured in two places Complete dislocation of occiput from atlas	Died instantaneously Medulla found divided at autopsy
15. McCarthy 1874	Fell head foremost down hold	Tetraplegia arms and legs	Atlas broken into 4 fragments Odontoid broken off	Died 3 1/2 days later Cold contracted no compression
16. May 1876	Fell 15 ft on to back of head	No definite cord signs fully recovered later	Fracture of posterior arch of atlas Odontoid broken off Rotary dislocation atlas on axis Fracture transverse processes 5th and 6th cervical vertebrae	Died 3 1/2 years later man dead, suffocated with piece of wire t Glove for first cervical nerve found absorbed at a top Cold normal
17. Eberman 1879	Fell from steps struck occiput against ground	Walked to his room supporting neck with hands	Fracture transverse process of atlas Fracture through body of C 3	Died in 30 minutes
18. Armstrong 1885	Man hit on back of neck or head by baseball bat	Died almost immediately	Fracture transverse process of atlas Rupture of azygos ligaments	Died in few minutes
19. Francis 1886	Man fell 20 ft striking upper and back part of head against a plank	Rigid neck paralysis left lower limb and both upper limbs	Fracture posterior arch of atlas Vertical fracture of axis through pedicles	Died 37 days after injury
20. Lannelongue 1883	Fell backwards off seat struck head on ground	Severe pain rigidity of neck Seventeen days later limbs paralysis began and he died in a few hours	Fracture anterior and posterior arches of atlas Odontoid process broken off at its base Transverse ligament intact	Died 18 days later
21. Boindt 1893	Fell forwards down steps	Diplegia right arm and leg, anaesthesia of left side (Brown Sequard palsy)	Transverse fracture anterior arch of atlas Odontoid broken off Rotary dislocation of atlas on axis	Died one month later Compression of right half of cord no loss lesion of brain stem recovered
22. Koehler 1895	Fell 10 ft on to head	None	Probable fracture of atlas and of odontoid	Recovered
23. Smith and Cleary 1893	Child fell off box seat head struck flexed under body	Kept alive for 3 hours by artificial respiration Tetraplegia	Fracture anterior and posterior arches of atlas Odontoid process broken off Transverse ligament intact	Died 3 hours later
24. Piquet (Billet case) 1920	Fell 11 ft	Difficulty in swallowing no limb palsies	Fracture of anterior arch of atlas Rotary dislocation atlas on axis	Recovered
25. Scott 1924	Hit on back of neck with heavy stick	None Walked about	Fracture of both arches of atlas in middle Odontoid broken off	Died 10 days later of tetanus Cold normal
26. Corner 1905	Museum specimen History unknown	—	Atlas missing in 1st healed fracture (1) comminuted fracture right lateral mass (2) fracture posterior arch in centre Atlas unaltered to occiput Fracture body of axis	Survived some time
27. Corner 1907	Fell off horse on forehead	Dysphagia and thick speech No affection of limbs	Fracture of anterior arch of atlas Rotary dislocation of atlas on axis Condition of odontoid doubtful	Recovered
28. Van Assen 1908	Fell 13 ft head foremost	No cord signs Occipital neuralgia	Fracture both arches of atlas Fracture of odontoid Rotary dislocation of atlas on axis	Recovered
29. Blackwood 1903	Fell 4 ft on to right side of head	Total paralysis below level of larynx Kept alive for 34 hours and 40 minutes by artificial respiration	Atlas fracture in three places both arches Odontoid broken off Dislocation of occiput on axis	Died 35 hours later Hemorrhage into cord from level of fourth magnum to third cervical vertebra
30. Lane 1908	Hit on back of neck with heavy timber head flexed	Concussion Diplegia both arms	Fracture of atlas Fracture of axis Forward luxation of atlas on axis	Recovered Palsies improved when seen 6 years later
31. Myster and O'ood 1910	Fell down 13 stairs	Severe occipital neuralgia No cord signs	Fracture of anterior arch of atlas Rotary dislocation of atlas on axis	Recovered
32. Myster and O'ood 1910	Railway accident	All four limbs became spastic 24 months after accident	Fracture posterior arch of atlas Complete dislocation of atlas on axis	Died suddenly 1 month after laminectomy and 5 months after injury No autopsy
33. Myster and O'ood 1910	Fell from a height on to right side of head and neck	Right occipital neuralgia Monoplegia right arm	Fracture posterior arch of atlas right side Rotary dislocation of atlas on axis	Recovered
34. Ischeb 1910	Fell 15 ft on to forehead	Diplegia right arm and leg, improved by laminectomy Palsy developed 24 months after accident Occipital neuralgia	Fracture lateral mass of atlas body of axis compressed Rotary dislocation of atlas on axis with which it is ankylosed	Recovered Seen 9 years later right hand weak leg recovered

ANASTOMOSIS OF RECURRENT LARYNGEAL TO  
PHRENIC NERVES

## SOME RECOVERY OF FUNCTION

BY

E. BROUGHTON BARNES, FRCS Ed.,

SURGEON TO THE EAR AND THROAT DEPARTMENT OF THE NORTHAMPTON  
GENERAL HOSPITAL,  
AND

SIR CHARLES BALLANCE, KCMG, MS, FRCS,

CONSULTING SURGEON, ST THOMAS'S HOSPITAL, LONDON

The following case of complete traumatic division of both recurrent laryngeal nerves was treated by anastomosis of each nerve to the phrenic nerve of the same side. Some recovery of function was, as will be seen, observed.

The patient, a woman 52 years of age, was seen by one of us in May, 1926. She was suffering from aphonia and attacks of dyspnoea. The vocal cords were completely paralysed, the patient was breathing through a very narrow chink, and there was constant stidor. The inner borders of the cords were slightly concave; tension was absent, and a slight flapping movement was observed during respiration. She was having frequent attacks of severe dyspnoea, during which she became cyanotic. She spoke in a voiceless whisper.

The history was that in October, 1925, she had been operated on in a hospital in another city for adenoma of the thyroid gland. Since that operation she had suffered from dyspnoea and cyanosis as above described. She was admitted to the Northampton General Hospital. As long as she remained quite quietly in bed on her back without attempting to speak no attack of dyspnoea occurred, but she was not able to take sufficient nourishment. The question of tracheotomy was considered, but it was determined to attempt treatment by nerve anastomosis.

*First Operation*

On June 5th, 1926, a general anaesthetic was administered by Dr J. P. Iraylen of Northampton. An incision was made along the anterior border of the sternomastoid muscle on the right side. It was seen then that a mass of scar tissue extended from the cricoid cartilage to the sternum. The recurrent laryngeal nerve was identified in the region of the inferior cornu of the thyroid cartilage and followed downwards in the scar tissue for 1½ inches. Beyond this point no nerve could be found. The portion of recurrent laryngeal nerve was then freed from the scar tissue and stimulated with the faradic current, but no movement of the right vocal cord was detected.

The sternomastoid muscle was now retracted backwards and the search for the phrenic nerve commenced. It also was embedded in scar tissue, but as the phrenic is a larger nerve than the recurrent laryngeal the difficulty of identifying it was not so great. It was then found that it was not possible to bring the end of the recurrent laryngeal nerve to the side of the phrenic so as to perform a recurrent laryngeal phrenic end-to-side anastomosis. A search was then made in the scar

for the descending nerve, for if this nerve could

31	Lane	1938	Hit on back could be divided and the following with heavy ent laryngeal phrenic anastomosis head fixed on phrenic anastomosis end to

34	Pfleger	1910	fell 15 ft. on to forehead and this smaller portion of the larger portion

FIG 1—Right side

for five eighths of an inch. It was then found that it was possible to bring this portion of the phrenic nerve across the cricoid sheath and unite it end to end to the recurrent laryngeal nerve without tension (See Fig 1). On stimulating with the faradic current the phrenic nerve distal to the region from which a portion of the nerve had been separated in order to unite it to the recurrent laryngeal the right half of the diaphragm contracted. There was no difficulty in maintaining a sufficient airway during anaesthesia, though there was a good deal of noise during induction and some stidor for one week subsequently. After the operation the left side of the epigastrium moved much more than the right side, indicating partial or complete paralysis of the right half of the diaphragm.

*Second Operation*

On July 3rd, 1926, a general anaesthetic was again given by Dr Iraylen. A similar operation was performed on the left side as had one month previously been carried out on the right side. The scar tissue was more extensive on the left side of the neck than on the right, and the operation was, if anything, more difficult. The identified portion of the recurrent laryngeal nerve was not more than 1 inch in length. The phrenic nerve was isolated and freed for some little distance. It was then drawn under the cricoid sheath and a recurrent laryngeal phrenic anastomosis effected, end to side by means of a very fine suture (see Fig 2). The tension on the incision in the phrenic caused it to gape, so a second suture was employed to close the gap.

FIG 2—Left side

The right half of the diaphragm still appeared to be paralysed, and the second operation paralysed the left half of the diaphragm.

*Prognosis*

By July 24th there was appreciable improvement in tone of the right cord. During August and September, 1926, the patient was gaining weight at the rate of about 1 lb a week. She had occasional slight attacks of dyspnoea until the end of July, but since then she has not had any difficulty with respiration except that she is still "short of breath" on exertion, such as climbing stairs rapidly. There had not been any laryngeal stidor since the end of July, 1926.

In August the patient left Northampton and went to live in Newcastle. On September 18th Mr W. F. Wilson reported "some definite movement and adduction of the right cord on attempting phonation, which is husky but distinctly audible, the left cord is motionless and apparently fixed in the mid position." At the end of September regular daily electrical stimulation, galvanic and faradic, across the larynx was begun. On November 8th Mr Wilson reported "there was definite movement on both sides of the diaphragm, which was well domed, and showed good muscular tone. The right cord moved better than the left, which had very little action though its arytenoid (left) showed a marked pivotal movement to the extent of crossing the mid line and pushing the right arytenoid away therefrom."

At the end of November the patient returned to Northampton and was seen by one of us. There was then definite movement in the right cord, strong adduction, and abduction amounting to about one quarter of the normal range. The tone in the left cord was obviously improved—in fact, good—but there was no convincing movement. The voice was a husky whisper, rather wasteful but with definite tone. One month later the right cord had not changed. The left showed definite adduction, but no definite abduction beyond the rebound.

In January 1927, the patient was admitted to Northampton Hospital for more frequent electrical treatment, galvanic and faradic, across the neck. She then had strong adduction in both cords and spoke in a loud husky whisper. The right cord had not changed since December but there was appreciable abduction of the left. She was instructed to stop breathing in expiration as long as possible five times thrice during the day, with the object of obtaining forced inspirations.

Movement of the left cord continued to increase, and by March 3rd 1927, the movement on the two sides was equal, about one third abduction on each side, adduction was strong

and phonation fairly good, though her voice was very uncertain in quality and pitch and changed with disconcerting suddenness. It was observed that if annoyed she spoke with a strong gruff voice, but under examination began to whisper again. On this date the patient was given a general anaesthetic and Killian's laryngoscope was used. The direct view of the cord confirmed the above findings. An attempt was then made by means of a curved and insulated electrode which was pressed into the pharynx, to cause contraction of the crico-arytenoid, posterior muscles, but no abduction of the cords occurred. The only movement observed was a very vigorous adduction of the cords. The adduction movement is the stronger movement, and may have overwhelmed the weaker contractions of the abductors, if this occurred.

Under deep anaesthesia a paradoxical movement of the vocal cord (inspiration adduction) was observed. This also has been seen in monkeys after this anastomosis has been done. The abductor muscles are very sensitive to deep anaesthesia. A second attempt, a month later (April 9th) to cause contraction of the abductor muscles by direct faradic stimulation was made but the result was as before. Strong adduction of the cords was alone seen.

On May 21st 1927, the right cord was as before with about one-third of the normal abduction but the left cord was obviously retrogressing adduction was still strong but there was no evidence of abduction beyond the rebound.

On June 8th 1927 the right cord was as before, the left cord was almost motionless in mid position, a slight adduction movement alone remained. For the first time since she was seen in May 1926 the patient spoke continuously in a fairly strong voice, not in a whisper while under examination. Her general condition is continuing to improve.

#### Remarks

The presence of an extensive area of scar tissue on both sides of the neck not only made the operations of great difficulty, but made us doubtful of a satisfactory result.

The patient had definite improvement in the tone of the right cord seven weeks after the operation. The inner border of the cord was straight and tense. She had no further attacks of dyspnoea. Subsequently (four months after the first operation) she had definite laryngeal tone in the voice and definite movement of the right cord.

Nine months after operation she sometimes spoke in a strong voice (we are of the opinion that there is a functional element in her aphonia) and had abduction of both vocal cords giving rather less than one-third of a normal glottis opening. Adduction was strong. Her general health was definitely improved though still far from good.

Nearly one year after the operation the left cord could no longer be seen to abduct. We are of opinion that the condition of the right cord is permanent. It has strong adduction and crosses the mid line, and abduction to one-third of the normal.

It may be asked, what has the patient gained by these anastomoses? The answer is that she has been saved from imminent suffocation, and even now go about the world without fear of sudden death, and that though the result is far from perfect, owing to the peculiar circumstances of the case, we think it is better than if the woman had been permanently sentenced to the wearing of a tracheotomy tube. She has also gained a fairly good voice.

The period of time required for the recovery of tone in the cord and the commencement of movement in the cord in this patient coincides with what has been observed in corresponding experiments in the monkey. In man when an end to side recurrent laryngeal phrenic anastomosis is done we recommend that the nerves should be placed behind and not in front of the carotid sheath.

It is to be noted that both halves of the diaphragm recovered their complete motility. The paralysis of the diaphragm did not appear to inconvenience the patient. Part of the right half of the diaphragm was probably recovering before the second operation was done.

The splitting of the phrenic nerve on the right side appeared to us an unsatisfactory method of anastomosis and one likely to be specially sensitive to pressure by scar tissue but it has given a better result than the end to side anastomosis on the left side. On the left side however tension at the anastomosis could not be avoided and tension at the site of nerve anastomosis may spoil the result of any such operation.

## THE EXPERIMENTAL PREVENTION OF STONE IN THE BLADDER IN RATS

BY

P. McCARRISON, C.I.F. M.D. D.Sc., F.R.C.P.,

LIEUTENANT COLONEL I.M.S.

DIRECTOR DEFICIENCY DISEASES INQUIRY, PASTEUR INSTITUTE  
COOYDOO, SOUTH AFRICA

In a paper in the JOURNAL of April 16th, 1927 (p. 717) the experimental production of stone in the bladder in rat was recorded. The composition of the calculus-producing diet was

Tinned Scotch oatmeal or <i>atta</i>	53 parts
Linseed meal	20
Tinned cornflour	25
Sodium chloride	1
Calcium phosphate	1
Distilled water	<i>ad libitum</i>

*Atta* is whole-wheat flour

The present report deals with the prevention of stone in the bladder in rats fed on an "oatmeal diet" of the above composition.

#### THE EXPERIMENT

Two groups of young rats 18 in each were selected, their aggregate body weight was the same—910 grams. There were 9 males and 9 females in each group. The body weight of the males ranged from 50 to 53 grams of the females from 46 to 52 grams, all were of approximately the same age. The 36 animals were confined in twelve precisely similar cages, 3 males or 3 females being placed in each. All were fed on the oatmeal diet and water, and were allowed to eat as much as they liked. One group received fresh whole milk in addition to the oatmeal diet, the other did not. A ration of 2 ounces of milk was provided for the three rats in each cage, but some secured more than their share.

The experiment was continued until the death of all animals receiving the oatmeal diet without milk, the last two animals died on the 150th day. The experiment was protracted for a further seventeen days in the case of the animals receiving milk in addition to the oatmeal diet. The survivors (15) on this regimen were killed by drowning on the 167th day. All animals were subjected to *post-mortem* examination.

#### RESULTS

The results of the experiment may be summarized as follows:

The animals fed on the oatmeal diet without milk grew badly, all died within periods ranging from 65 to 150 days. Nine (50 per cent) were found at *post-mortem* examination to have stones or gravel or both in the bladder—usually with, but in one case without, cystitis. Cystitis was present in one case without associated stone or gravel. The stones ranged in weight from 2.4 to 99 mg. The sequelae of calculus (dilated ureter, hydronephrosis, and pyonephrosis) were not present in any case in this series nor was stone found in the ureter or kidney. In one animal a large grey-white pear-shaped fibrous mass was present in the bladder, the thin end being drawn out into a fine thread which extended into the urethra. This condition was associated with haematuria. Bloody urine was passed by two other animals in one of which cystitis was present in association with a number of minute stones (gravel). The three animals in which haematuria was observed prior to death were found at *post-mortem* examination to have suffered from severe anaemia associated with a lemon yellow tinting of the skin and cutaneous tissues. Three of the 18 rats in the group died of pneumonia, in 5 others no cause of death could be found except asthenia.

The animals fed on the oatmeal diet with milk grew well as a rule though one better than others. There was no doubt due to the fact that some of them secured more of the milk ration. Two died of pneumonia and one of an unknown cause. The other 15 remained in good health.

This abstract is published by permission of the Director-General Indian Medical Service. The full paper will appear in the Indian Journal of Medical Research.

Neither stone in the bladder nor gravel, or cystitis, or any abnormality of the urinary tract was found at post-mortem examination in any of these 18 animals

#### CONCLUSION

The addition of whole milk, in the proportion of two-thirds of an ounce per rat daily, to a diet capable of causing urolithiasis in 50 per cent of young rats, completely prevented the development of phosphatic calculi

## THE BACTERICIDAL ACTION OF LIGHT ON TUBERCLE BACILLI

BY

ALBERT EIDINOW, M.B., B.S. LOND

(From the National Institute for Medical Research, Mount Vernon, Hampstead)

THE value of ultra-violet rays in the treatment of lupus vulgaris is well established, but the mechanism of their mode of action is still a matter of controversy. Some maintain that the local application of light produces direct bactericidal action in the depths of the lupus nodule. If there is no direct bactericidal action of these rays, some general effect on the whole body or the local effects of irradiation must be responsible for the results and cures which have been obtained.

While bacteria can be readily destroyed by exposure to light, the culture medium, the depth of layer of fluid, the age of the culture, the intensity of light, and temperature are all important factors. Coliform bacilli suspended in Ringer's solution are readily destroyed by long ultra-violet rays, staphylococci by short rays, while, according to Weisner,<sup>1</sup> the Friedländer pneumo-bacillus is resistant to light owing to the mucous envelope surrounding the organism. Robert Koch<sup>2</sup> found that cultures of tubercle bacilli were destroyed by prolonged exposure to sunlight which passed through the window glass of his laboratory. J. Bang showed the bactericidal action of the concentrated Finsen light on the tubercle bacillus, and the *Staphylococcus pyogenus aureus*. Mmo V. Henri<sup>3</sup> and Brioni investigated the effects of irradiation of tubercle bacilli with the mercury quartz arc, and found that the bacilli lost their acid-fast staining reaction after three to four minutes' exposure, and were destroyed after ten minutes. Kattenbinder found that tubercle bacilli were readily killed after five to sixty seconds' exposure to the iron arc. Such experiments have definitely proved the bactericidal action of ultra-violet rays on the tubercle bacillus, but in the case of sunlight the effect of ultra-violet rays has not been clearly separated from heat effects. Thus, results obtained from the experiments of Mitchell and Crogh,<sup>4</sup> von Beigen, Trishnokaja, and Fr. Kiusus show variations in the lethal time from half an hour to six hours.

While concentrated solutions of tuberculin are resistant to light,<sup>5</sup> solutions of 1 in 1,000 concentration can be weakened by exposure to rays shorter than 3,250 Å. Recently W. Hausmann,<sup>6</sup> W. Neumann, and K. Schuberth have shown that inoculations of irradiated tuberculin do not give rise to any local reaction, but the usual general reaction is obtained.

As the review of the literature indicated that the tubercle bacillus can be destroyed by ultra-violet rays, but failed to demonstrate the selective region, further investigations were carried out. Surface scrapings of a fourteen-day culture of tubercle bacilli (a virulent bovine strain obtained from Captain S. R. Douglas) were placed in a sterile test tube, 250 mg. of this culture were mixed with 250 ccm. of sterile saline, and quantities of 50 ccm. of the mixture were placed into sterile vaccine bottles and sealed off.

#### EXPERIMENT 1—Control

Four guinea pigs were inoculated subcutaneously into the right thigh with 1 ccm. of the suspension of tubercle bacilli in saline (dose=1 mg. of tubercle bacilli). The animals were kept under observation and the time of the appearance of a hard swollen inguinal gland was recorded. Forty-one days after inoculation all the animals were killed and post-mortem examinations were performed. All these animals had generalized tuberculosis.

#### EXPERIMENT 2—Exposure of Tubercle Bacilli to Mercury Vapour Lamp (7,620-2,300 Å U)

Of the emulsion of tubercle bacilli in saline 15 ccm. were placed in a sterile quartz flask. The flask was attached to an electric motor and was exposed to two mercury vapour lamps (H.B.B. type, 25 amperes, 210 volts, D.C.) eight inches distant. The flask was slowly rotated during the exposure, so that a thin fresh film of fluid was constantly exposed to the lamp. The flask was kept cool during rotation by a trough filled with cold water. At intervals of 5, 10, 15, 30, and 60 minutes samples of the suspension of the irradiated bacilli were removed from the flask and 1 ccm. of each specimen inoculated into a guinea pig. The experiment began on December 20th, 1926, and ended on January 31st, 1927, when the animals were killed.

Time of Exposure to Lamps	Weight	Weight when Killed	Result when killed
	Grams	Grams	
5 minutes	5.0	—	Died December 24th 1926 ? cause pneumonia
10	330	520	No evidence of tuberculosis
10	330	603+	Small caseous gland 2 by 0.5 by 0.5 cm.
15	370	590	Healthy when killed
15	450	590	No histological evidence of tuberculosis
30	310	420	
30	510	600+	
60	390	430	Healthy
60	410	510	

**Conclusion**—The tubercle bacilli suspended in saline are destroyed after 10 minutes' exposure to the irradiations (7,620-2,300 Å U) of the mercury vapour lamp.

#### EXPERIMENT 3—Exposure of Bacilli to Mercury Vapour Lamp (Filtered)

Tubercle bacilli were exposed as in experiment No. 2 to radiations of a quartz mercury vapour lamp, but filtered through a screen of vitreous glass (radiations=5,720-2,800 Å U). The experiment began on December 12th, 1926, and ended on January 31st, 1927, when the animals were killed.

Time of Exposure to Rays	Weight	Weight when Killed	Result when killed
	Grams	Grams	
5 minutes	350	450	Two small caseous glands 1 by 0.5 by 0.7 cm. and 1.5 by 0.5 by 0.7, otherwise nil
5	360	360	Big caseous glands nodule in spleen
10	375	560	Small caseous inguinal gland
10	330	540	Small caseous inguinal gland 1 by 0.5 by 0.5 cm.
15	420	570	Nil
15	390	390	Small caseous inguinal gland 1 by 0.75 by 0.5 cm.
30	350	603+ (pregnant)	Nil
30	325	470	Nil
60	380	510	Nil
60	360	570	Nil

**Conclusions**—The tubercle bacilli in saline are destroyed or attenuated after 30 minutes' exposure to the rays (5,720-2,800 Å U) of the mercury vapour lamp filtered through a sheet of vitreous glass, which allows the passage of rays from 5,700 to 2,800 Å. There was evidence of a local lesion at the site of inoculation in the right groin, in the animals injected with the tubercle bacilli exposed for 5, 10, and 15 minutes. When the animals were killed on January 31st, 1927, only one guinea-pig (No. 15) showed a microscopic tuberculous nodule in the spleen. No macroscopic or microscopic evidence of the disease was found in the remaining animals, which were injected with suspension of bacilli exposed for 30 and 60 minutes.

#### EXPERIMENT 4—Exposure of Bacilli to Mercury Vapour Lamp Through Window Glass

The suspension of tubercle bacilli in saline was exposed to the rays of the mercury vapour lamp as in Experiment 2 but through a screen of window glass (radiations=5,720-3,300 Å U). At intervals after 5, 10, 15, 30, and 60 minutes' exposure samples

were removed from the flasks and inoculated subcutaneously into guinea pigs. The experiment began on December 20, 1926 and ended on January 31, 1927 when the animals were killed.

Time of Exposure to 3300 Å	Weight in Grams	Weight when Killed	Culture and Bacteriological Post mortem Examination
5 minutes	315	370	Generalized tuberculous nodules in spleen liver lung, and glands
5	310	470	" "
10	510	530	" "
10	253	370	" "
15	350	570	" "
15	325	470	" "
20	700	570	" "
20	200	370	" "
30	370	470	" "
60	375	510	" "

**Conclusions**—These rays (5,720-3,300 Å) have no lethal action on tubercle bacilli in saline after 5 to 60 minutes' exposure.

**Experiment 5**—A second control experiment on four guinea pigs showed the virulence of the tubercle bacillus suspended in saline and kept in the cold room at 5° C for twenty-four hours.

**Experiment 6**—Another control experiment showed the virulence of the tubercle bacillus suspension mixed with an equal quantity of rabbit's defibrinated blood.

**Experiment 7**—A third control experiment showed the virulence of the tubercle bacillus suspension mixed with an equal quantity of rabbit's serum.

**Experiment 8**—A suspension of tubercle bacilli in saline mixed with defibrinated blood was exposed to ultra-violet rays as in Experiment 2. All the animals showed tuberculous lesions.

**Experiment 9**—A similar experiment was carried out with the irradiated mixture of suspension of bacilli and rabbit's serum and with like result.

#### Conclusions

Tubercle bacilli mixed with blood or serum exposed in a very thin film are not killed.

Similar experiments carried out with mixtures of defibrinated rabbit's blood and staphylococci have shown that bactericidal action is noticeable after half an hour's irradiation of the thin blood film, and complete destruction of the cocci after one hour's exposure.

These experiments afford evidence that rays shorter than 3,300 Å are the most bactericidal on the tubercle bacillus. The long ultra-violet rays from 4,000 to 3,300 Å were without effect. Since the penetration of shorter rays is small it is doubtful whether local bactericidal action occurs in vivo with either the local Finsen lamp or the Kromayer types of local treatment lamps. The fact that the whole range of rays from 5,760 to 2,300 emitted from the mercury vapour lamp cannot destroy tubercle bacilli in a thin blood film even after one hour's exposure strongly supports this view. Nagelschmidt inoculated guinea pigs with extracts of tuberculous tissue which had been irradiated with the local Finsen lamp. He claimed that the animals inoculated with the irradiated tuberculous tissue survived, while control animals inoculated with unirradiated tissue died. Klingmüller and Halberstädter irradiated lupus nodules for seventy minutes with a Finsen concentration lamp and injected ground extracts of the irradiated lesions into the peritoneum of guinea pigs. Some of these animals died later from tuberculosis. Similar experiments were carried out with virulent tubercle bacilli injected subcutaneously and intraperitoneally, and the site of inoculation was immediately irradiated, but later all the animals were found to be suffering from generalized tuberculous disease. They concluded from their experiments that the local Finsen light treatment had no local bactericidal action even when the tubercle bacilli were situated comparatively near the surface. H. Jansen has found that the rays from the Finsen lamp can completely destroy tubercle bacilli in a lupus lesion to a depth of 0.15 mm, but the lupus nodules are usually situated 2 to 4 mm below the skin surface. Karl Sonne and Axel Rehn both state that the increased skin temperature which is produced with local irradiation sup-

ports the increases of Thiele and Wolf, that at higher temperatures longer wave length rays can exercise bactericidal action. Seeing that tubercle bacilli mixed with blood or serum are not destroyed in vitro it seems very improbable that any irradiation with the mercury vapour lamp of tubercle bacilli in vivo can result in a direct bactericidal action. With many of the lupus lesions the extensive scar tissue ulcerates and degeneration under a lethal action still is probable. The local Finsen light is overheating the part, may therefore have some bactericidal action.

The cure of lupus vulgaris by means of local irradiation must be due chiefly to its reaction. The histological changes following the irradiation of lupus lesions have been studied by R. Grunl and indicate an inflammatory reaction in the early stages and, later, necrosis of the chronic granulomatous tissue with the formation of connective tissue. Many theories have been advanced to explain the results which have been obtained, but no definite experimental proof has been yet described which can explain the reaction of the tissues following the general irradiation of the skin of the body or the local application of the rays to the site of a tuberculous lesion. While the chronic tuberculous diseases of the skin and mucous surfaces respond admirably to ultra-violet radiation, the tubercle bacillus is an organism which is more resistant to the rays of the mercury vapour lamp than the staphylococcus and apparently is only sensitive to the shorter ultra-violet rays and from these in vitro it is protected by the tissues.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL.

#### TUBAL ABORTION AND RUPTURE

AFTER reading Dr. Connell's most interesting paper on tubal abortion and rupture (June 4th, p. 1004) I felt that the following case might be of interest as it differs so completely from other cases which have fallen to my lot.

Early on August 22nd 1926 I was called to see a married woman aged 32 with one child aged 2 years. She gave a history of several similar attacks. On this occasion he had awoken at 5 a.m. with severe abdominal pain. Her husband gave her some brandy which failed to ease her. A period had started two days previously it was a week overdue. She had always been quite regular until this occasion. The loss was much the same as usual. Her colour was good and there was certainly no pallor. The temperature was normal and the pulse 82. There was pain and tenderness in the right iliac fossa. I persuaded her to come into hospital for observation. Internal examination added nothing to my knowledge. She was given an enema. The result was good and she felt much better. I assumed that the appendix had emptied itself and settled down. This evening I found her lying up in bed chatting quite happily to the matron and feeling almost well. The next day she felt quite well. The second day after admission—at the end of four days—the period appeared which he considered normal. She had no further to say and I removed the appendix as she had had no more of the attacks. Stipulating that I should remove it even if it looked normal. I told her that I expected it would look normal after such a short attack and promised to remove it. She kept perfectly well until the operation on September 4th. When I reached the peritoneum I saw free blood on the other side of it. I opened the peritoneum, removed the appendix which was fairly normal, had a laceration of the wound and started afresh in the middle line. There was plenty of free blood around it. When I started to close it I found to my surprise that it was the left tube which had ruptured. I removed it and a very small incision. The patient made a very good recovery.

The points which seemed most striking were that the onset of bleeding and pain did not synchronize more closely and that when I saw her between three and four hours from the onset of the pain there was no pallor or collapse. It is true that she had some brandy. Her highest temperature was 98.8° F. on the evening of her admission to hospital and I should have expected more from peritoneal irritation by the free blood. The signs and symptoms pointed to the right side, and the ruptured tube was the left.

PETER BUTTERWORTH

## SHRAPNEL FRAGMENT IN TONSIL

The following case seems to be worthy of record

A man, aged 30, consulted me for a sore throat. Both tonsils were enlarged and injected, the right more than the left. His temperature was  $101^{\circ}\text{F}$ . I sent him home to bed, and prescribed the usual remedies, but although the temperature dropped to normal in two days the right tonsil still remained swollen and painful. On examination of the throat I saw a black speck, about the size of a pin's head in the right tonsil which seemed hard and resistant to a probe. I cut down on this, and removed a jagged piece of shrapnel about the size of a small bean.

Upon questioning the man, he told me that he had a shrapnel wound in his face in 1918, the point of entry being just above and in front of the right angle of the jaw.

Ardleigh, Essex

## LARYNGEAL SPASM ASSOCIATED WITH PERITONSILLAR ABSCESS

The following notes of an alarming and seemingly rare complication, occurring during the course of quinsy, appear worthy of record.

A youth of 18 years, who had suffered from quinsy on two or three previous occasions, developed an inflammatory swelling of the left peritonsillar tissues which went on to abscess formation. On the afternoon of the second day of this inflammatory process he awoke suddenly from sleep and experienced great difficulty in breathing, it was most marked during inspiration, which was long drawn out and accompanied with a high pitched wheezing noise. Expiration was prolonged, but was not so difficult as inspiration. The facial expression showed alarm and distress, eyes staring, face pale and covered with perspiration. This attack lasted from five to ten minutes and passed off as suddenly as it came, leaving respiration easy and natural. Two similar attacks of lesser severity and shorter duration occurred on the following day. The attacks ceased after the evacuation of pus on the fourth day.

The facial swelling was typical of peritonsillar abscess, with the usual displacement of the adjacent soft palate and uvula, but at no time did the swelling or displaced palate or uvula threaten to occlude the opening of the oral pharynx. There was no appreciable oedema of the palate or fauces.

These attacks would appear to have been due to paroxysmal constriction of the larynx, oedema of the glottis would scarcely be so sudden and transient.

The patient stated that his mother, owing to a throat affection, had to have "an opening in the neck" to enable her to breathe. It is possible that this recollection, together with the associated dread of imaginary suffocation, may have been instrumental in producing spasm of the larynx.

Surgeon Lieutenant R.N.

## BLOOD TRANSFUSION IN HAEMORRHAGIC DISEASE OF THE NEWBORN

The memorandum in the JOURNAL of June 18th on blood transfusion in haemorrhagic disease of the newborn impresses the fact that authorities are so much agreed on the usually fatal termination of this condition, in the absence of such treatment, that a case of spontaneous recovery is worth recording.

On Christmas Day, 1926, I was called to the wife of a seaman, in labour with her third child who was delivered of a healthy female infant weighing  $7\frac{1}{2}$  lb. The next morning I was informed by the nurse in attendance that the child had passed a considerable quantity of blood in the morning evacuation, but unfortunately the stool had not been preserved. At 10 a.m., however, I was able to examine a further stool, which contained a large quantity of rusty fluid, accompanied by a few small black clots and a little bright red stained mucus. There was no vomiting or any other abnormal symptom, and as no other cause for the bleeding could be found a diagnosis of melena neonatorum was made. I immediately prescribed a mixture of 1 minim of the tincture of ferric chloride in water to be repeated hourly, and no other treatment was given. The child passed several more motions the same day, all containing similar matter to the one described, but was perfectly normal in every other respect. The next morning the quantity of blood in the stools was considerably diminished, and the third motion was entirely free from such matter. As there is no recurrence of the haemorrhage and the child continued to gain weight, the treatment was discontinued on the evening of the third day and the infant made an uninterrupted recovery. Seen six months later the child was perfectly healthy in every respect.

I am indebted for permission to publish this case to Dr M. G. Lucas of Hull.

Leeds.

## NINETY-FIFTH ANNUAL MEETING

OF THE

## British Medical Association.

Held at Edinburgh, July, 1927.

## THE SECTIONS.

## BRIEF SUMMARY OF PROCEEDINGS

ARRANGEMENTS have been made to publish, during the next few months, full reports of the discussions in the Sections of the Annual Meeting at Edinburgh. Meanwhile, the notes printed below and those which will appear next week will enable members who were not present to gain a general view of the proceedings. Any errors to which attention may be drawn will be corrected in the full reports.

## SECTION OF MEDICINE

Wednesday, July 20th

RESULTS OF INSULIN THERAPY IN DIABETES MELLITUS. PROFESSOR HUGH MACLEOD (London), opening the first discussion in this Section, emphasized the fact that in discussing the effect of insulin treatment it was essential to eliminate those cases of so-called diabetes in elderly people with glycosuria but no ketosis, such cases were not really true diabetes, and the patients often responded quite satisfactorily to dietetic treatment without insulin. Analysing his cases before the introduction of insulin treatment Professor Macleod found that on the average no patient with true diabetes was likely to survive for more than five or six years on dietetic treatment alone, whilst in severe cases two or three years was the most that could be expected. Taking a series of 291 cases of typical diabetes treated in the Medical Unit of St. Thomas's Hospital in the four years since 1923, when insulin became available, the records showed that up to date only twelve patients had died. Several were admitted in coma, all of those living were now doing well, including two with tubercle bacilli in the sputum. Of the twelve fatal cases, one patient developed coma and died outside the hospital, one died in coma in the hospital, having failed to respond to insulin, three recovered from coma but died of cardiac failure, the others died of various complications. These results gave a death rate of only 4 per cent, whilst, judging from the older figures, it seemed probable that without insulin not more than one-third of these 291 patients would still be alive. Speaking of the difficulties encountered, Professor Macleod said that if acute infection supervened the insulin dosage must be greatly increased. In young children great care must be used, but the outlook was very hopeful, although he had as yet seen no cases in which improvement had been sufficient to enable him to discard insulin, if intercurrent disease, to which children were so prone, was accompanied by an aggravation of the diabetic symptoms, the insulin must be increased at once. Insulin had revolutionized diabetic surgery, if properly handled the diabetic had now about as good a chance as the normal patient undergoing an operation. Professor Petten (Sweden) discussed the cause of the rising mortality rate in spite of insulin treatment, and said that the figures for Holland showed that the rate was actually falling in cases up to the age of 50, and that the whole rise occurred above the age of 65. He kept his patients on the diet used by Joslin with low protein content, and only permitted a daily ration of 50 grams of carbohydrate. He did not give glucose in coma. Dr R. D. Lawrence (London) dealt with failures under insulin treatment, some patients either would not or could not carry out their instructions, in some a severe complication developed, such as carcinoma of the pancreas, but he had been less successful than the previous speakers in cases of coma. In circulatory failure intravenous saline with small doses of adrenaline had proved very helpful.

Dr P. J. Crumbridge (London) classified cases of glycosuria into three groups: (1) "achiatric," with defective utilization of sugar, (2) "anapothetic," with defective

storage and (3) "epithymic," with low renal threshold. In the second class insulin was rarely needed, and in the third it was contraindicated. Dr O Ixton (London) also dealt with the failures of insulin. Tuberculous patients did well until secondarily infected, then went rapidly downhill. His experience suggested that some cases of true diabetes certainly did recover with careful treatment—his own percentage of recoveries was 2—and further, that diabetes under insulin treatment was not a progressive disease. Professor Murray Lyon (Edinburgh) gave as his indications of the administration of insulin (1) clinical acidosis (2) severe emaciation (3) limit of sugar tolerance insufficient to maintain a useful life (4) inability to clear sugar after careful diet. He thought it essential to free the urine from sugar in all cases, and did not object to three daily injections for this purpose.

Professor Blum (Stasbourg) laid stress on the importance of searching for latent tuberculous before treatment. In coma he gave large doses of insulin 40 to 50 units intravenously half-hourly if blood-sugar examinations were impracticable the condition was controlled by urine examinations and by noting with extreme care the clinical reaction. Alkali in small doses was necessary, as there was a diminished Na content in the organs in coma. Dr G. Graham (London) showed by statistics that the increased mortality rate was entirely due to a rise in cases between the ages of 60 and 70. He disagreed with Professor Maclean in separating the elderly glycosuric patient as not a true diabetic. Dr C. G. Lane suggested that in some cases there was a difficulty in the diffusion of glucose into the cells, and he considered that it was the glycosuria that must be controlled rather than the hyperglycaemia. Dr F. B. Smith (Harrogate) warned against too hopeful prognosis in the treatment of diabetes in cases of psychoneurosis.

#### SECTION OF SURGERY

Wednesday, July 26th

##### TUBERCULOSIS OF THE KIDNEY

SIR JOHN THOMSON WALKER, opening the first discussion in this Section, said that the mortality of nephrectomy in renal tuberculosis had fallen from 25 per cent in 1900 to 3 per cent at the present day. He gave an account of his own methods of diagnosis and how the extreme difficulties in advanced cases could be overcome. After dealing with spontaneous healing and its significance he passed to treatment, advocating nephrectomy except when the disease was bilateral or pulmonary tuberculosis was present. Co-existent bone or joint disease or genital tuberculosis did not negative operation. He did not think removal of the whole ureter was necessary; he advocated suture of the wound without drainage. He employed tuberculin for two years after nephrectomy. Dr Polher (Levin) advocated heliotherapy but only as an adjunct to surgery. The outlook was rendered better by pre-operative preparation in this way and by subsequent exposure to sunshine, particularly in those cases where the wound itself subsequently became infected with the tubercle bacillus. Mr A. Fullerton (Belfast) reported 158 cases of the disease; he believed in nephrectomy and had had no deaths among his last 38 operations. He gave particularly interesting account of those cases which were not cured by nephrectomy and of a series of patients treated by non-surgical measures alone. He also demonstrated his method of catheterization of the ureters by iliac exposure of them. Mr H. Wade (Edinburgh) pleaded for the use of x-rays and pycelography in diagnosis; he did not consider it necessary to search for the bacillus in the urine. Post-operative frequency of micturition could be abolished sometimes by excision of a single callous ulcer of the bladder. Mr J. F. Dobson (Leeds) found it possible by exposure of the ureters in cases where cystoscopy did not give information to tell by simple inspection the condition of the corresponding kidney. It was neither necessary nor desirable to open the ureter to insert a catheter. Mr B. J. Ward (Birmingham) laid stress upon the presence of pus in the ureteric specimen. He considered the indigo-carmine test unreliable. Dr E. Ward (Paignton) mentioned that post-mortem evidence of the healing of tuberculous disease of

the kidney could be found if looked for. Mr H. Temple Murrell (Johannesburg) emphasized the desirability of treatment in early stages. He was convinced of the value of lithium salts. Mr P. Gordon Craig (Sydney) reported two cases of spontaneous cure of the disease and recommended epidural anaesthesia to facilitate cystoscopy.

##### DIAPHRYCTOMY FOR ACUTE OSTEOMYELITIS

Mr W. Pankin (Glasgow) gave an interesting lantern demonstration of the treatment of acute osteomyelitis by primary diaphryctomy and exhibited patients to show what good and speedy results could be obtained by removing the shaft in acute osteomyelitis in children under the age of 12. He emphasized the extreme importance of the after-treatment. Mr R. Kennon (Liverpool) thought that the radiograms showed evidence of new bone formation before the operation was performed and therefore from a surgical point of view the case had been allowed to go on too long. Mr M. Mahmoudian (Ashton-under-Lyne) thought diaphryctomy unsuitable for early cases of humeral and femoral shafts, which inhibited bone formation after treatment was of vital importance. He advocated early bone grafting. Mr R. Ollerton (Manchester) performed the operation for the fibula or ulna but not for the femur, because he had obtained bad results.

#### SECTION OF OBSTETRICS AND GYNAECOLOGY

Wednesday, July 26th

##### RELATION OF PREGNANCY TO GENITAL DISEASE

The first discussion in this Section was opened by Professor Munro Kerr (Glasgow), his paper being devoted to cardiac disease. He said that some of the functional disturbances which might occur were undoubtedly mechanical from pressure of the enlarging uterus; others were caused by disturbed innervation, alterations in metabolism or secretory activity of the endocrine gland. In organic disease opinion was unanimous that it was the condition of the heart muscle which determined the gravity of the lesion. In the most recent discussion on the subject there was a general consensus of opinion about such questions as the gravity of the condition, the distressing signals manifested and the treatment to be employed. Their experience in Glasgow was that cardiac disease exacted a heavy toll of its victims; the figure generally agreed upon being somewhere between 15 and 25 per cent. Disturbances of the free chest increased respiration rate, crepitations at the bases of the lungs, breathlessness on slight exertion were often more important signs than occasional irregularity that a heart was finding the strain too great. Should no improvement result after a week of medical treatment then the pregnant should be terminated. With aortic lesion the condition was generally very serious; so operative treatment should not be too long delayed. In mitral regurgitation it was seldom difficult to decide when a patient might be safe to continue her pregnancy. He regarded cases of mitral stenosis as the most difficult to gauge but he always agreed with grave concern in a case which displayed marked cardiac irregularity, crepitation and breathlessness which could not be relieved by simple measures. Obstetric treatment should on no account be delayed so long. In many cases shortening of the second stage by forceps delivery was all that was required but in others artificial termination of the pregnancy was urgently necessary. When it was necessary to deliver the patient in the early months he was convinced that vaginal Caesarean section was the operation of choice. In the late months, however, could often be safely and promptly employed in multiple cases but in primiparae and in case of prolonged second stage he favoured abdominal Caesarean section. Dr I. P. (Preston) dealt with the question of tuberculous. He hoped that a very necessary separation of the disease in early stages of pregnancy might coincide with the termination of infection. He did not think that the ill effect of pregnancy upon a tuberculous subject could now days be derived. When statistics were based on reliable diagnosis they invariably showed that symptoms were aggravated and that quietest lesions flared up. For obvious reasons in the majority of cases tuberculous was not suspected before pregnancy had occurred. He was not in favour of inducing

abortion, since this might influence tuberculosis as unfavourably as confinement. He was strongly in favour of artificial pneumothorax, the results of which were so good that on no single occasion had he regretted performing it. Dr J. Brown (London) reviewed the influence of venereal disease on pregnancy. He estimated the frequency of syphilis at about 7 per cent. He described the signs most commonly met with in the mother and the foetus, and urged that treatment should be begun as early as possible, that the patient should be treated with arsenical preparations in every subsequent pregnancy, and that treatment might be safely continued up to the time of confinement. Even then there could be no guarantee that the child would not be a congenital syphilitic. He condemned the practice of vaginal douching in cases of gonorrhoea, preferring thorough swabbing of the vagina and cervix with a silver preparation or picric acid in spirit. He spoke favourably of detoxicated vaccines. Professor Gibbon FitzGibbon (Dublin) related his experiences with curative cases. Professor Sir Ewen Maclean (Cardiff) disagreed with Dr Rist's pessimistic views regarding tuberculosis in pregnancy. Professor Mellroy (London) thought that Professor Leitch's conclusions as to the gravity of curative lesions were rather exaggerated. She did not approve of Caesarean section and sterilization of the patient. Dr Mary Macneil (Edinburgh) thought that the outlook in syphilis was good, whereas in gonorrhoea the reverse was the case. Dr Mackenzie (Tain) described his experiences as a rural practitioner. Dr Paramore (Rugby) advocated hysterectomy in cases where Caesarean section was necessary. Professor McKerron (Aberdeen), Dr Lees (Edinburgh), and the President also took part in the discussion.

## SECTION OF PATHOLOGY AND BACTERIOLOGY

Wednesday, July 20th

### GROWTH IN ITS PATHOLOGICAL RELATIONS

DR ARCHIBALD LEITCH (London) discussed the reproductive powers of cells shown in physiological replacement, in repair, and in neoplasia, and maintained that the growth property in all was an inherent attribute differing only according to the restraint imposed on this power. He was inclined to regard this growth substance as some factor that could be transuded occasionally from the cells to act as a stimulant on other cells, and it was maintained at the expense of the other cell functions. The more specialized the cell the less growth power it could exhibit, and the more malignant the process of growth the less differentiated in function the cells became. Cells incapable of regeneration in adult life were incapable of neoplastic growth. The exceptional tumours that went against this general law were due to developmental defects, and he suggested that such growths actually started as tumours in embryonic life. Although the virus theory of cancer offered an easy solution of many puzzles, yet critical experiments undertaken by himself and others give no support to the theories of Gye or of other upholders of the parasitic hypothesis. Professor Robert Muir (Glasgow) said that although in tissue cultures the growth of cells could be stimulated by chemical substances present in embryonic extract, it was doubtful if analogous cell stimulants occurred in nature, even these tissue culture stimulants were more in the nature of food substances than anything else. It was difficult to believe that in the ordinary processes of repair the regeneration was started by cell stimulants or arrested by their exhaustion. He held that any growth-promoting substance came from within the involved cells themselves, and it was peculiar that proliferation started in cells at some distance from the area of wound resection. With regard to tumours he was prepared to accept the possibility of a special class of neoplasms due to a filterable agent, and believed that this class would be enlarged in the future. Two other groups must be admitted: (a) a class of tumours due to chronic irritation which required a long period for their development, and (b) tumours due to developmental defects characterized by early and rapid growth and by an extraordinary complexity of structure. Professor Shaw Dunn (Manchester) considered that though neoplasms might differ considerably from each other yet they had more in common than any

of the processes of a reactive type. The striking units of neoplastic diseases suggested, if not a single cause, a similarity of causal factors. The great mass of tumours arose without any apparent cause, but knowledge of causative factors in others was increasing. The experimental production of cancer by special irritants suggested that processes of chronic irritation, not yet clearly defined, might be responsible for many tumours. The development of cancer in cirrhotic livers and in scars led to the belief that such tissue derangements rendered cells liable to neoplastic formation. Though some tumours might be rare, as Dr Leitch had shown, yet they could not lightly be discarded on that account in considering the question of origination. The liability of simple tumours to become malignant was much greater than published cases would suggest, and the supervision of malignancy was not an entirely new phenomenon but an extension of the process in existence. He emphasized the factor of hereditary liability which entailed the admission of some extraneous agent in addition to a congenital innate property of cells. He could not accept the idea of anything in the nature of a micro-organism as playing a part in the production of neoplasia. Professor M. J. Stewart (Leeds) discussed the relation between cysts and tumours, and held that such segregations were no more liable to neoplasia than normal tissues. Epithelial heterotopias of the intestinal tract betrayed no tendency to the development of cancer. He was prepared, however, to believe that segregations of cells within organs, not displaced organs, might possess a dormant power, and, passing through a resting stage, might later blossom out into malignancy. Professor J. H. Kettle (Cardiff) thought that the increasing knowledge of growth processes deepened the mystery and prevented a broad general view being taken of the whole question. He could not agree that hyperplasia, benign, and malignant tumours merged into one another. Growth and cell proliferation were not interchangeable terms, nor in tumour formations were we justified in regarding all tumours as due to the same etiological factors. Professor Miller (Kingston, Ontario) called attention to the frequent presence of multiple foci of new growth independent of each other. He emphasized the possible production of malignancy by hormones, acting in particular the development of chorion epithelioma. Professor Lorrain Smith (Edinburgh), President of the Section, remarked that in the process of growth in the skin a cell divided into two in the basal layer, one remaining there and the other developing and differentiating in other layers finally to result in scales. How was this determined, so that one was left and the other taken for differentiation? Was this already determined in the process of division? Similarly in the development of blood corpuscles from haematoblasts. The arrest of this was related to cancer growth, as, for example, in basal cell cancer.

## SECTION OF THERAPEUTICS AND PHARMACOLOGY

Wednesday, July 20th

### ADMINISTRATION AND USES OF OXYGEN

PROFESSOR J. A. GUNN (Oxford), President of the Section, opened the first session of this Section with a few remarks, after which Dr H. Whitridge Davies (Leeds) read a paper on oxygen therapy, using Barcroft's classification of the "anoxic," the "anemic," and the "stagnant" types. In the anoxic type deficiency of the blood in oxygen was usually associated with some pulmonary lesion. The lack of oxygen in the anemic type was due to shortage of haemoglobin in the blood, whereas in the stagnant type too little blood reached the tissues, interfering with their oxygen supply. Oxygen administration was chiefly of value in pneumonia, pulmonary oedema, acute bronchitis, and emphysema. Dr Davies thought that the oxygen chamber method when properly used was valuable, though not altogether free from risk, such as fire. It was particularly useful when patients could not tolerate the usual mask, and when continuous inhalation was required. He critically reviewed some of the usual methods of administering oxygen, condemning the ordinary funnel method, approving the use of the nasal catheter, but preferring the procedure introduced by Haldane, which resulted in the saving of about 50 per

cent of oxygen. He described in detail a form of apparatus devised by himself, and enumerated three criteria of successful oxygen administration—namely, the abolition of cyanosis, the relief of dyspnoea, the fall of the pulse rate. In the absence of Dr W. T. Ritchie (Edinburgh) his paper was read by Dr C. G. Lambie (Edinburgh). Dr Ritchie thought that the chief value of oxygen administration was the relief of dyspnoea, too little oxygen was generally used in view of its rapid absorption. He emphasized the importance of continuous administration and of giving at least two litres of the gas each minute. He defined the conditions in which it was of no value, and added that in circulatory failure oxygen played only a small part, except in the later stages when pulmonary oedema was in evidence. Dr R. Hilton (London) confined his remarks to the uses of oxygen in congestive heart failure and pneumothorax. He illustrated the uselessness of the ordinary funnel method, but approved the employment of the nasal catheter in some cases.

Professor J. A. Gunn (Oxford) in a paper on expectorants deplored the very small advance in this subject during the last fifty years. Hardly any experimental work had been performed, and present-day practice was mostly based on tradition. This was due to the difficulty of making exact measurements of the bronchial secretion. He compared the two varieties of classification of stimulants according to (1) their physiological effects and (2) their sedative or stimulant action. The second, although extensively used even in modern textbooks was in his opinion bad. The physiological classification was more scientific, it included the groups (1) reflex stimulation through gastric irritation, (2) central stimulation (3) action on the secretory vagal ends, (4) stimulation of the gland during exertion.

## SECTION OF DISEASES OF CHILDREN

Wednesday, July 20th

### ACUTE PNEUMONIA IN EARLY CHILDHOOD

THE President, Professor John Fraser, in his opening remarks, made sympathetic reference to the late Dr John Thomson. Dr Charles McNeil (Edinburgh) introduced the discussion by giving an analysis of 558 hospital cases of pneumonia observed personally by him during the past seven years. Half were in children under the age of 2, and in these the mortality was 30 per cent. In the age period 2 to 12 years the percentage of deaths was 5.7. The explanation of the disparity in mortality lay in the frequency of bronchopneumonia in infants. The difficulty of distinguishing clinically between the two types was admitted, and stress was laid on two signs—duration of fever and rapidity of resolution. In seeking for an explanation of the frequency of bronchopneumonia in early childhood—it was desirable to recognize the importance of natural age constitution and the effects of bad environment and hygiene. Further bacteriological research was necessary. It was suggested that the nature of the pathological process would be emphasized by the substitution of the terms "alveolar" for "lobar" and "interstitial" for "broncho" pneumonia. Dr Agnes Macgregor (Edinburgh) referred to the incidence of the two types in 100 consecutive fatal cases. Of these, 81 were in children under 2 years of age and 89 were examples of bronchopneumonia. In bronchopneumonia there was a progressive invasion of the lymphatic system and interstitial framework of the lung by the infective agent, which accounted for the slow resolution. Further effects of the lymphangitis were suppuration within the lungs, bronchiectasis, and fibrosis. Predisposing factors were of great significance. Diminution of the incidence of bronchopneumonia might follow an attack upon them. Dr L. Findlay (Glasgow) inclined to the view that all primary pneumonias in children under the age of 3 should be regarded as bronchopneumonia in type. In a recent pathological investigation of 65 of his fatal cases there was only one example—and that in a child of 5—of typical lobar pneumonia. Variation in the host rather than in the type of infecting agent was the more important from the etiological standpoint. Dr J. H. Thursfield (London) reviewed the attempt to find a specific method of treatment and gave details of a series

of severe cases of primary pneumonia treated by means of a sensitized pneumococcal vaccine. The results were encouraging. Lieut.-Colonel W. Glen Leitch (Edinburgh) referred to an investigation into the bacteriology of bronchopneumonia in children. Using a special medium, he obtained a growth of Pfeiffer's bacillus from the lungs and blood of the great majority of the cases. He held that this bacillus played a primary part in the breakdown of the defensive force. Dr A. Carmichael (Edinburgh) suggested that the bronchopneumonia of early life was the expression of the lobar pneumonia of later years. He referred to cerebral and abdominal types. Dr C. P. Lapage (Manchester) pleaded for a clinical investigation in which the help of the general practitioner might be enlisted. Dr Armand-Dehillo (Paris) spoke of the assistance to be obtained from fluoroscopic examination. Dr H. C. Cameron (London) deprecated any tendency to regard the attempt to distinguish between the two great types of pneumonia in infancy as unprofitable. The presence of delirium was characteristic of the lobar form as was the finding of dullness at an early stage. Dr A. G. Newell (Harrington) strongly advocated vaccine therapy. Dr C. W. Yining (Leeds) commended open air treatment, continuous oxygen inhalation, and judicious feeding during the acute phase. Dr F. M. Cardner Medwin (St. Asaph) suggested sodium nucleate intramuscularly as a routine procedure. Dr S. P. Huggins (High Wycombe) gave his experience of vaccine treatment. Dr Wilkie Scott (Nottingham) thought that a classification based upon either mortality or morbid anatomy gave a false impression of the incidence of the two types of pneumonia. Dr Helen Mackay (London) discussed the preventive aspect. The President considered that immuno-transfusion had a distinct future.

## SECTION OF MENTAL DISEASES

Wednesday, July 20th

### CHRONIC SEPSIS AS A CAUSE OF MENTAL DISORDER

AT the request of the President of the Section (Professor G. M. Robertson) Dr Hamilton Marr took the chair. At the first meeting of the Section Dr William Hunter (London) opened the discussion on chronic sepsis as a cause of mental disorder. He admitted that septic conditions were not the cause of all mental disturbance, but considered that there were clinical grounds for recognizing a definite "septic psychosis" and he described an illustrative case in which no improvement occurred over a period of two years until septic teeth were removed. He referred to the remarkable increase in the recovery rate which followed the treatment of the discoverable infective focus in Cotton's cases, and advocated the provision of adequate facilities in mental hospitals for treatment along the lines suggested by these results. Sir Berkeley Moynihan (Leeds) emphasized the influence of chronic sepsis on the production of lesions of the abdominal viscera citing as an example "no cholelithiasis without antecedent infection." He had often removed foci of infection such as the gall bladder in "functional psychosis" with the happiest results. Dr Chalmers Watson (Edinburgh) believed that much could be learned from the study of the oral cavity and gastro-intestinal tract generally by bacteriological methods. Dr Groves described a case of recurrent mental illness in a girl after a very extensive campaign of detoxication including non-specific protein therapy. She recovered mental health and became physically stronger than she had ever been previously. Dr D. K. Henderson said that chronic sepsis had not been neglected in mental hospitals but it was not permissible to speak of a septic psychosis. The work of Kopeloff, Kirby, and Clancy was the best controlled and did not support Cotton's contention that the majority of psychoses were largely the result of chronic sepsis. Dr W. F. Menzies (Cheddleton) stated that most bacteria had two strains—a hemolytic and a neurotoxic. Dr Watson-Williams quoted cases which showed a relation between focal infection and mental illness. Dr W. A. Potts (Birmingham) believed that there was a definite "septic psychosis." Dr Hurter, in reply, said he considered that Kopeloff had not proved his point.

Friday, July 22nd

## REPORT OF THE LUNACY COMMISSION (ENGLAND)

Under the chairmanship of Dr. Hamilton Main, Professor G. M. Robertson (Edinburgh) opened the discussion with a tribute to the thoroughness and efficiency with which the Royal Commission had done its work. It was a striking reply to newspaper propaganda that the Commission had not found a single case of improper detention. Nevertheless, the fear of improper detention had obsessed the laymen of the Lunacy Act of 1890. Of the two questions, of medical treatment and legal detention, the latter in the past had occupied the foremost place and had hindered treatment. In Scotland it had been conclusively demonstrated that personal intervention by laymen in the process of commitment to a mental hospital was unnecessary. Patients had been divided into two classes for the purposes of the Commission: the voluntary and the involuntary. The measures advocated by the Commission for the second group were of debatable value. That the recommendation of only one doctor should be required in the provisional treatment order was a mistake. It was also creating a difficulty to make the application of the provisional treatment order depend upon prognosis—upon whether the patient would recover within a certain time. It would injure the patient's prospects of recovery to place him at once under a reception order, for that would be equivalent to giving a gloomy prognosis. The Scottish Schedule G was cast in much better shape than the formula suggested by the Commission. It was profoundly to be regretted that the Commission should advocate the personal intervention of a justice in the proceedings for a provisional treatment order. Direct judicial intervention was unnecessary, whether from the point of view of improper detention or from the necessity for conforming to the canon of English law that the liberty of the subject may not be infringed without the intervention of some judicial authority. Scottish experience confirmed this. The sheriff never saw the patient, but simply inspected the application and the medical certification. There had been no case of improper detention under these rules within the last seventy years. This happy state of affairs had been helped by the fact that provision was made in Scotland for appeal to two independent medical men: a similar provision would have avoided many of the Commission's difficulties. Finally, the justice should be replaced by the Board of Control.

Dr. E. Mapother (London) denied that there was any clear-cut distinction between the voluntary and the involuntary case. Where a voluntary case passed into a condition in which solution was impossible the recommendation of the Commission would place him under a provisional order at the end of a month. A provisional order and full certification were virtually identical. The fact that under the provisional order a magistrate had to see the case within seven days would drive practitioners to the use of an urgency order. Dr. T. B. Haslop (London) said that certification often led to the labelling as insanity what was fundamentally an endocrine or metabolic anomaly. It was well known that magistrates were often very unwilling to perform the duties imposed on them by the Lunacy Acts. He remembered one magistrate who, when asked to see a patient with a view to signing an order, said, "This is awful. I know nothing about it." (To the patient) "Madam have you any delusions?" Dr. W. F. Menzies (Cheddleton) stated that the provisional order would involve three successive personal examinations of the patient by the judicial authority. The management committee of each mental hospital should be appointed *ad hoc* as the judicial authority. Dr. Risien Russell (London) said that two distinct issues were involved—doctors could get protection against action for damages only if they were prepared to accept the interposition of a legal authority, and if they were prepared to give evidence on oath. The intervention of the law did not necessitate publicity. To have someone trained both in medicine and law as the judicial authority would make the matter too medical. There were three prime desiderata: there should always be two doctors concerned, the judicial authority should always see and examine the patient and also the

doctors, the doctors should give their evidence on oath and be subjected to cross-examination like any other witnesses. Dr. Ross (Lochgilpherd) referred to the simplicity of the procedure in parts of Switzerland: "Chaque loi pour les aliénés devient un loi contre les aliénés."

Lord Russell said that a great difficulty was constituted by the public suspicion of doctors regarding certification—a fact which legislators had to bear carefully in mind. To appoint the committee of a hospital as the judicial authority would simply fan this suspicion. While a formal court "case" must be avoided, the Commission had the strongest evidence of the desire of patients to state their views in an inquiry. To make a general practice of retaining as an involuntary patient a man admitted on a voluntary basis who had lost solution might prejudice the whole voluntary principle. Sir David Drummond said that Lord Russell had admirably expressed his (Sir David's) own views. Sir Frederick Willis said that the Government were very anxious to bring in new lunacy legislation. It was very pernicious that intended patients could not at present obtain treatment till after they were certified. In Sir Frederick's opinion adequate safeguards were possible without a justice, but the public demanded his intervention. At present the justice was sometimes no safeguard at all. Further protection was necessary for doctors. It was a pity that doctors should give evidence against one another. No case of the wrongful detention of a proper patient had come before the Commission, although only one certificate was required. Sir Arthur Rose (Chairman of the Board of Control in Scotland) hoped that progressive legislation would soon be enacted in England as that would facilitate the passage of still more progressive legislation for Scotland. Dr. C. O. Hawthorne declared that the stigma lay in the certificate. Doctors must be protected. At present partnership agreements were being drawn up in which a provision was made that neither partner should ever sign a lunacy certificate. This represented a sentiment which must be respected in legislation. Doctors alone were competent to judge when there was a disorder and how it should be dealt with. When the State assumed authority it must also assume responsibility. The doctor should have the immunity conferred upon other witnesses. Dr. Hubert Bond recalled that when a committee was appointed in 1884 to inquire into the workings of the Lunacy Acts, the Earl of Shaftesbury felt this to be an attack on his administration of these Acts, and resigned the chairmanship of the Commissioners. To the Earl of Shaftesbury the intervention of a justice was anathema. It was doubtful whether, if Lord Shaftesbury had lived, such intervention would ever have been permitted to be incorporated in the Act of 1890. Dr. Briggs said that in Massachusetts over 95 per cent of the patients committed were never seen by a magistrate, and in only one case had a physician been sued (unsuccessfully). The appearance of medical men on opposite sides of a case was now virtually avoided by referring the patient to two expert alienists, whose reports became available to both sides. Dr. Main then declared the discussion closed owing to limitation of time.

## SECTION OF NEUROLOGY

Wednesday, July 26th

## THE TICS AND ALIEN CONDITIONS

During the first discussion, Dr. S. A. Kinnier Wilson (London) referred to the confusion that still existed in regards "involuntary movements." A host of ill-differentiated expressions bewildered the student, and the first duty of the clinician was to separate such classes of movement as appeared to have distinctive characters. Dr. Wilson dealt in turn with the different definitions of a tic that had from time to time been advanced, such as Cruchet's, and Meige and Reindel's. Passing to the symptomatology, he especially stressed the abnormal mental state characterized by volitional instability, and in not a few instances by a degree of mental infantilism. The localization and varieties of tics were only limited by the number of functional acts of which they might be the counterpart and that number was legion. Various facial tics were perhaps the commonest. In tic phenomena there

was a psychical predisposition. In some, possibly the majority of cases, the tic made its appearance as the expression of an unconscious desire, or of a desire that was often but half hidden from consciousness. Tics rarely accompanied hysteria, nor were they manifestations of that psychoneurosis. Movements of defence against some source of irritation sufficed in some instances to set in motion the processes leading to a tic. Prognosis depended upon the degree of volitional impairment of the patient. The older the patient and his tics, the less favourable were the chances of relief. Treatment lay in adopting general hygienic measures and a disciplinary regime, in some cases certain sedative drugs and hypnotic or other form of suggestion were of value. Probably the best form of treatment was that known to the French school for the better part of a century—re-education or muscular drill. Professor Guillemin (Paris), after paying a graceful compliment to British neurology, discussed the etiology and pathology of spasmodic torticollis. Dr A. F. Hurst (Aberdeen) dealt with the visceral tics, including acrophagia, certain types of cough, particularly those met with in association with asthma—sniffing etc. Professor Guichet (Bordeaux) spoke on certain symptoms in connexion with 'tic' and associated mental states. He also gave an admirable exposition of the different forms of treatment. Dr B. Sachs (Boston), while agreeing that tics had a manifold etiology, regarded the majority as of psychogenic origin. They were invariably associated with a peculiar mental instability of which the tic might be the only symptom. Rigorous discipline was necessary in treatment. Dr A. Stanley Barnes (Birmingham) thought tics were commoner in childhood and adolescence. The temperament of the individual was the main determining factor, but mental stress might act as an exciting cause. Dr Grainger Stewart (London) doubted if acrophagia was really a tic. He was inclined to regard it as an hysterical state. Benefit to some tics sometimes resulted from reviving a forgotten memory under hypnosis, in other cases co-ordinating exercises were of value. Dr R. G. Gordon (Bath) considered that many tics might have a physical basis, such as muscular rheumatism of the trapezius causing torticollis; it was necessary, therefore, to exclude all physical factors by careful examination. Dr P. Cloake (Birmingham) raised the question of the different physiological levels of the nervous system at which tics and other involuntary movements might occur. Dr Poyle referred to cervical arthritis as a cause of tic of the head, and Dr Brock also spoke

of difficulty of ophthalmoscopic differentiation. He reviewed generally the three clinical types: papillary oedema, neuritis optica, and retrobulbar neuritis, and described in detail the pathological anatomy of retrobulbar neuritis, the most striking features of which were an irregular plaque formation in the substance of the nerve and the destruction of the medullary sheaths before the axis cylinders. He gave an account of the condition of choked disc with sudden initial blindness and the affections of the optic nerve in myelitis, etc. entering into the pathology and the changes in the fields of vision. Dr A. J. Ballantyne (Glasgow) dealt with cases in which the oculist could give help in diagnosis, to the general physician or surgeon. In this connexion optic neuritis presented itself mainly under two aspects: (1) as the papilloedema associated with such conditions as intracranial tumour and meningitis, and (2) in renal disease. He described a case of unilateral choked disc due to tumour; the optic neuritis in cerebro-spinal meningitis (he had found 5 instances in 61 cases in the epidemic of 1907), and cases due to injury, loss of blood, and the toxæmia of pregnancy. He also discussed the relation of retrobulbar neuritis to renal disease. He was inclined to be conservative as regards operation. The discussion was continued by Professor J. van der Hoeve (Leiden), Drs H. M. Traquair (Edinburgh), Young, and de Schweinitz (Philadelphia), Professor W. H. Wilmer (Baltimore), Dr Wilder, Sir William Lister, Sir J. H. Parsons, and Sir George Berry.

#### DEVELOPMENT AND DISEASES OF THE RETINA

The second day was occupied by short papers. In a communication on the comparative development of the retina Dr Ida Mann (London) discussed the differentiation of the retinal layers and stated that there was a definite sequence of events which held good in all vertebrates so far examined. She described the formation of the amacrine cells and showed drawings and slides of the development of the retina in cyclostomes, fish, amphibians, reptiles, birds and mammals. Her paper was discussed by Dr H. Pönné (Copenhagen) and Professor J. van der Hoeve (Leiden). Sir William Lister (London) in a paper on the treatment of detachment of the retina concluded that in retinitis striata, diffuse fibrous degeneration of the vitreous and in cases with a hole treatment was practically useless. Fibrous bands might be divided and the associated retinitis or choroiditis might be treated. All cases in which the mechanism of the detachment was not determinable should be treated by rest measures, calculated to promote absorption of the interretinal fluid, such as subconjunctival injections and hot-air bath, and if no improvement occurred, by scleral puncture. Dr W. Clark Souter (Aberdeen) discussed spontaneous reattachment of the retina and described six cases in three of which choroidal atrophic changes had followed and in two retinitis striata, while one showed an apparently normal fundus. He considered the pathological findings in published cases which had come to the microscope. These papers were discussed by Drs Kerry Pönné, Pönné, Tudor Thomas, Sir Arnold Lawson, and Mr Inglis Pollok.

#### MISCELLANEOUS PAPERS

Sir Arnold Lawson (London) spoke on the value of anti-septics, describing in detail his pre-operative and theatre technique. He considered it impossible to sterilize the conjunctiva. The most reliable danger sign was the presence or secretion. He valued farviscinity as a prophylactic but did not find it of value when infection had developed. His paper was discussed by Mr Bluff Harman. Mr Holt Dugdale (Manchester) described an investigation into the nasal or lacrimal obstruction and its treatment by intranasal means. He found the presence of nasal abnormalities and discharges. The rectification of nasal lesions, with the exception of suppurative ethmoiditis, did not relieve the obstruction and patients rarely gave a history of nasal trouble. There was certainly a nasal cause for lacrimal obstruction but the pathology and incidence needed further investigation. In a paper on 'obscure amblyopia' in Edinburgh and Glasgow Dr H. M. Traquair (Edinburgh) gave figures showing that in the last thirteen years the average percentage of

##### OPTIC NEURITIS

The proceedings of the first day were occupied by a discussion on optic neuritis, which was opened by Dr J. V. Paterson (Edinburgh), the President, Dr A. H. H. Sinclair, being in the chair. After a reference to the confused nomenclature, Dr Paterson stated that classification should rest on the investigation of causes as a whole and not merely on disc appearances. Cases due to raised intracranial pressure were recognizable by the amount of swelling of the disc and the absence of visual disturbance in the early stages. In their diagnosis he considered the use of the Gullstrand ophthalmoscope, study of the rays of the skull and the visual fields and the co-operation of a neurologist essential. Palliative trephining should be performed early and by a specially trained surgeon. The second group of cases was due to inflammation in the nerve or sheath. Disc changes might be present but considerable failure of vision was almost invariable and recovery the rule. Some of these cases were due to disseminated sclerosis, but in many no cause was ascertainable. Cases of nasal origin did occur but he did not believe that it had yet been proved that the ordinary case of retrobulbar neuritis was due to spread of infection from the nose. He mentioned optic neuritis following head injuries, myelitis and the rare sudden acute cases with extreme loss of vision. Dr H. Ronne (Copenhagen) in a long paper, discussed the confusion with regard to the nomenclature of the various types of neuritis and the

those attending the eye departments of the Royal Infirmary was 1. The monthly incidence showed a peak in spring and early summer with a pronounced fall in winter. Graphs from these figures were compared with graphs from statistics of arrests for drunkenness due to alcohol and methylated spirit. Then dissimilarity indicated the inference that the rubbishy must be regarded as entirely due to tobacco. The paper was discussed by Mr. Bishop Horman, Dr. Young and Dr. Schwenitz (Philadelphia). Time did not permit the reading of the President's paper on intracapsular extraction of cataract, but he demonstrated his method of operating in the theatre on four cases.

## SECTION OF LARYNGOLOGY AND OTOTOLOGY

Wednesday, July 20th

### IMMOBILITY OF THE VOCAL CORDS

DR. BROWN KELLY (Glasgow) illustrated the anatomical factors underlying paralysis of the vocal cords with lantern slides showing the various situations in which the laryngeal nerves might be pressed upon or suffer from trauma, especially in the base of the brain, and in the neck and chest. He referred to the various syndromes of Tumor, Vernet, and Hughlings Jackson, showing by means of diagrams and sections how the various associated lesions were brought about. He referred to the lesions of the laryngeal nerves due to endocrine affections, mentioning a curious case of injury to the nerve by traction over the ligamentum arteriosum. Mr. H. Tilley (London) described the clinical and mechanical aspects of paralysis of the vocal cords, based on the investigation of 23 cases. In past times a diagnosis of aneurysm or other fatal disease might have been made in such cases, but many of these patients had been known to recover. In one case seen twenty years previously the cords were paralysed, requiring urgent tracheotomy, and the patient was still alive and well. Mr. Tilley defined some of the causes of paralysis of the vocal cords, drawing attention to inflammatory factors in the fixation of the crico-arytenoid joint, and asked for an expression of opinion from the meeting as to the occurrence of this in the left cord. Sir St. Clair Thomson (London) said that there were many stages of impaired mobility before complete immobility was reached, he cited cases which he had seen in Midhurst Sanatorium over a period of ten years. Out of 500 cases 10 showed no tubercle, but one or other cord was immobile, these might have been due to thickened pleura or to gland pressure. Six out of 10 patients recovered, but the other 4 had still a fixed cord. Professor F. R. Nager (Zurich) referred to cases of paralysis of the cords due to goitre, and said that a benign goitre did not affect the cords. If in goitre the cords were affected malignancy was present, except when benign goitre suddenly enlarged with exercise, the involvement was then temporary only. As regards the surgery of goitre, 7 per cent of cases had paralysis of the cord, but this paralysis did not always recover. Professor Nager drew attention to cases of paralysis due to aneurysm of the innominate artery. Sir James Dundas-Graham related a case of bilateral abductor paralysis which remained unexplained until chronic rheumatoid arthritis developed. He also described a case which cleared up after bronchoscopy. Dr. J. S. Fraser (Edinburgh) contributed a statistical analysis, made by Dr. Lambert of Manchester, of 181 cases of paralysis of the vocal cords, and gave an interesting account of the various causations of the paralysis.

## SECTION OF PREVENTIVE MEDICINE

Wednesday, July 20th

### UNIFICATION OF PUBLIC HEALTH ADMINISTRATION

PROFESSOR P. S. LELAND, President of the Section, took the chair at the first meeting, and Dr. A. S. M. Macgregor (Glasgow) opened a discussion on the question whether all public health administration, municipal, school, factory, etc., should be concentrated under a single department and

the immediate control in each executive area be vested in a single individual. The administration of the public health services of the country was, he said, admittedly defective, and the confusion was added to by the mass of increased responsibility thrown upon local authorities by recent legislation. In the larger districts the new measures necessary had been taken, but in smaller areas this had been impossible. Efficiency was proportional to the size of the unit. Professor E. L. Collis (Cardiff) dealt with the question from the point of view of the factory medical service, the administration of which by the municipalities he considered quite impracticable. Hitherto the medical service had been imposed upon industry by the State, and there had not been the development there might have been under better conditions. Improvements must originate from the owners with the assistance of the State, factories must provide their own medical service, as they did their engineering service. Professor F. E. Wynne (Sheffield) thought factory medical service and the port sanitary service might be excluded from a scheme of unification which was otherwise most desirable. The proposal was only a revision to the recommendation of the Royal Commission of 1869. It would lead to a reduction in the number of inspectors, and accordingly to economy of effort and money. It would make records of individuals continuous, and therefore of some value. It was most important that junior members of the public health service should have an opportunity of engaging in every branch of the work. A memorandum sent by Professor D. W. Hope (Liverpool) was read in his absence by the secretary, Dr. W. T. Benson. Emphasis was laid on the necessity of uniting the health activities of the various Government departments, and on remembering the clamor of the Poor Law authorities, who had done so much in the provision of hospitals, and were still charged with the administration of vaccination. It seemed obvious that administrative control should be vested in a single committee with its own expert advisers. There had already been amalgamation of authorities in several cases in the London area. Dr. J. H. Meikle (Edinburgh) thought that united action would be secured only by compromise. In promoting big schemes as much might be lost as was gained. In Edinburgh co-operation and exchange of information between the public health authority and the school medical service had hitherto solved all difficulties. Dr. F. Dittmar (Scottish Board of Health) said the time had come when all medical work, both in connexion with infectious disease and general disease, should be undertaken by the local authority. This had recently been effected in Aberdeen, where the City Council had taken over the Poor Law hospital service. Dr. Kay Menzies (London County Council) described the organization of public services in the London area, which worked well as far as results were concerned, though it involved overlapping, friction, undue correspondence, and extravagance. The difficulty was to find the ideal unit, and conditions varied so much that each area should be left to work out its own scheme. Dr. W. F. Deardon (Manchester) said factory administration concerned the factory population, not the whole community, and could not be satisfactorily dealt with by the municipality. Dr. J. Middleton Munton mentioned several instances of the confusion which arose as between counties and county boroughs. He believed in the fundamental necessity of having one authority for all health purposes. Dr. Kinloch (M.O.H., Aberdeen) explained that in that city the Poor Law hospitals had been voluntarily handed over, without charge, by the parish councils to the city council. He did not agree that the factories should be excluded from any schemes of amalgamation. The sanitary inspector should be responsible for factory hygiene, and experts in environmental hygiene might be appointed. Dr. H. Semfield (Sheffield) gave instances of partial co-ordination in Gloucester, Essex, Cardiff, and Eccles. Dr. Bardsley, speaking as a member of the Poor Law Committee of the Association, pointed out that unification was already the policy of the Association, but such unification must start at the centre. Dr. Latham (London) urged the necessity of giving junior members of the service a training that would qualify them to take the position of head of a combined department.

## SECTION OF PHYSIOLOGY AND BIOCHEMISTRY

Thursday, July 21st

## STRUCTURE AND FUNCTION OF THE SPLEEN

THE morning discussion of this Section was opened by Professor Tut, who said that the circulatory system was everywhere lined with endothelium, except in the spleen, liver and the bone marrow, in which it was defective or absent. When foreign particles or micro-organisms were introduced into the blood stream they rapidly disappeared from the circulation, finding a resting place in these three localities, their disappearance was due to their ingestion in the spleen, liver, and bone marrow by the special phagocytic cells which here lined the blood channels. The curious circulatory arrangements of the spleen and its steady persistence throughout the vertebrate group indicated some special function. The splenic arteries ramified into fine non anastomosing penicillar vessels, each of which terminated in a small cluster of ellipsoids, which were phagocytic organs capturing foreign particles and effete blood corpuscles, and here the arterial endothelium came to an end. This region of the spleen was active in altering the corpuscular content of the blood. Blood in contact with the splenic reticulum was not induced to coagulate. The only other tissue in which this obtained was endothelium. As contact of the blood with ordinary connective tissue induced rapid coagulation, Professor Tut termed reticulum and endothelium haemostatic implying that these tissues might freely touch blood, whereas the other tissues of the body were haemostatic and might not touch blood. Examination of the splenic architecture showed that all its haemostatic tissues—namely, its capsule and trabeculae, veins, arteries, and Malpighian corpuscles—were screened from contact with the blood by means of a casing of reticulum. These last facts could be well demonstrated by injecting Indian ink backwards through the splenic vein. The ink painted all the reticulum of the parenchyma, leaving the haemostatic structures unpainted. Professor J Barcroft (Cambridge) reviewed the relation between the nervous system and the vascular function of the spleen, and demonstrated the effects of various stimuli upon the form and size of the organ. Professor P T Herring (St Andrews) pointed out the relation of the spleen to the lymph and haemolymph glands, and suggested the importance of the lymphoid tissue present in the spleen. Sir Humphry Rolleston (Cambridge) asked for information about the factors controlling the blood supply of the organ, and mentioned the rarity of tumour formation. Dr H C Hou (Peking) reported experiments in which the spleen was divided into two sections—(a) normal, and (b) denervated. He agreed that exercise diminished the size of the spleen even in the denervated portion, and suggested that the effect was due to adrenaline. Sir Edward Sharpey-Schafer (Edinburgh) drew attention to experiments which proved that the spleen was the most sensitive organ to adrenaline. Sir Berkeley Moynihan (Leeds) dealt with some effects of the removal of the spleen, and asked for greater co-operation of the physiologist with the clinician. Sir Albroth Wright, Dr Hackett, Dr Duncan Scott, and Professor Murray Lyon also spoke.

Following this discussion Professor P T Herring (St Andrews) read a paper on the comparative histology of the pineal gland. This was followed by a joint paper by Professor J A MacWilliam (Aberdeen) and Professor G Spencer Melvin (Cambridge) on optimal rhythm in the mammalian heart and the action of the cardiac nerves. A paper by Dr C Reid (Aberdeen) on the mechanism of voluntary muscle fatigue was read. Experiments were described, and it was suggested that the fatigue had a central origin due to impulses passing up the afferent nerve. Professor D Murray Lyon and Dr W Robson (Edinburgh) contributed a joint paper on exsanguina-

## INTERNAL SECRETIONS AND SEX CHARACTERS

Dr F A E Crew (Edinburgh), opening the afternoon discussion emphasized the physiological activity of the gonads as a condition of the normal development and maintenance of such of the sex dimorphic characters as are

secondary gonads. He said that the criterion of a secondary gonadic character was that it reacted to the physiological activity of the gonad in a particular definite way. It was established that the gonadic influence punctuated the growth of the long bone thereby affecting the general proportions of the body that it influenced the development and functioning of the central nervous system, affected the processes of general metabolism and exercised a strong and definite influence on certain structures and functions which constituted the commonly recognized sex-dimorphic characters. The development and maintenance of many morphological, epiological and physical characters were dependent upon the integrity and functional activity of the gonads. He said that it was possible to feminize a male by castration, and subsequent implantation of ovarian tissue. The latent homologous sex characters, such as the mammary glands, were stimulated into activity, and the heterologous—for example, the penis, prostate, and seminal vesicles—remained undeveloped or became diminished in size and complexity. Similarly it was possible to masculinize a female by ovariectomy and subsequent implantation of testis. He thought it clear that the ovarian and testicular hormones were sex specific, acting only on those structures with which each was normally associated. In artificial hermaphrodites could be produced by combining in the same body both kinds of gonadic tissue. He thus concluded that in the mammal the most distinctive sex dimorphic characters were the secondary gonadic, and that for the development and maintenance of these the presence or functional gonadic tissue was necessary. Professor E E Glynn (Liverpool) considered the influence of suprarenal cortical tumours on the ovary (inhibiting menstruation) and on the secondary sex characters (producing virilism). He said that hypernephroma did not produce sexual precocity in either boys or girls; the precocity involved only secondary sex characters. There was no evidence that suprarenal hypernephroma in males produced feminization. Dr A S Parkes (London), Professor P T Herring (St Andrews), Dr W P Kennedy (Edinburgh) and Dr L C Dunn (Storrs, Connecticut) also took part in the discussion.

## SECTIONS OF PATHOLOGY AND BACTERIOLOGY AND COMPARATIVE MEDICINE

Thursday, July 21st

## IMMUNITY

At a joint meeting of the Sections of Pathology and Bacteriology and of Comparative Medicine presided over by Professor T J Mackie (Edinburgh) a discussion on immunity was opened by Dr R A O'Brien who reviewed the recent advances in immunity from the point of view of practice. He was followed by Professor C H Browning (Glasgow), who considered the advances in the theoretical conceptions of immunity with special reference to antigen-antibody reaction, the part played by immunity phenomena in chemotherapeutic action and Lürlich's reception hypothesis. Professor Robert Muir (Glasgow) expressed the opinion that the specific relation of an antigen to antibody was the essential point and that it seemed to be more a chemical than a physical phenomenon. The names of varieties of antistances should not be considered as of 'definite' kinds—they were rather 'non uniform' bodies. Antigen function seemed to depend on extremely minute peripheral differences and the distinction of antigen and antibody was extremely important. This latter consideration might account for the greater effect of a haemolytic antibody on red blood cells in vivo than in vitro. Professor Ogilvie (Philadelphia) discussed the relation of sensitization to immunity and said that both anaphylactic and local reactions seemed to be important whether antigen or antibody was injected. Colonel W F Harvey presented a report on the work in India, showing that single doses of a vaccine produced less immunity than several that some immunity was apparent within a week, that full immunity was reached within three weeks, that its duration was longer than was generally believed, and that the reinoculation dose was smaller than even the smallest required originally might be. He suggested that future research might show that an animal

once immunized was in a sense always immunized. Professor Mathieson discussed the salient points of immunology as applied to veterinary practice. Dr H. D. Wright (London) said that the classical view of antibody activity—direct or indirect—was generally acceptable in toxin-producing organisms, but in other cases, such as pneumococcal infection, immunity might well be cellular. An important question was how highly immunized animals became infected. Many of the septiciemias might be largely accidental and due to the breakdown of a focal infection. Dr W. H. Andrews said that veterinary pathology differed from human in having an essential economic outlook. Professor T. J. Mackie (Edinburgh) said that antibodies were only the manifestations of the reaction to foreign proteins, and "natural immunity" could seldom be attributed to their presence. Antibody research had drawn immunology into the domain of colloidal and physical chemistry, and until this line was stripped of its importance no great advances would be made into "resistance." Immunity might well depend on sessile rather than on humoral agents, and the further study of tissue antagonism to bacterial agents and their products should prove fruitful.

#### SECTION OF DERMATOLOGY

Thursday, July 21st

##### ULTRA-VIOLET RADIATION IN DERMATOLOGY

Dr S. B. Dore (London), opening a discussion on the uses and limitations of ultra-violet radiation in dermatology, doubted whether many cases of lupus were cured by light treatment alone, surgical measures and selective caustics were still necessary. It was, no doubt, a valuable stimulant of the growth of hair in alopecia areata but by no means a specific. In psoriasis the results were irregular, benefit often resulted, but by no means invariable, and relapses were frequent. In acne suppuration could be controlled to some extent, but better results were obtained by x-rays. Cases of impetigo and staphylococcal infections, also of chronic septic and tuberculous ulcers resistant to ordinary measures, were benefited by light. The combined local and general use of light therapy gave much better results than local treatment by light alone. Factors in its action might be activation of cholesterol in the skin and increase of haemoglobin, leucocytes, and of the bactericidal power of the blood. The psychological effect of the treatment should not be forgotten. He did not expect any benefit from the provision of ultra-violet-passing glass for dwellings in smoke-laden cities, as the quantity of ultra-violet radiations which penetrated the atmosphere was extremely small. The cooling power of the air, obvious in Edinburgh, was also a factor of importance in using the rate of basal metabolism. Dr F. Guddner (Edinburgh) said that too much stress could not be laid on the psychological side of the treatment. They had treated at the Royal Infirmary 171 cases of tuberculosis of the skin in the light department since 1924, of which 27 had been declared provisionally cured, and 65 improved, the remainder were still under treatment. Tuberculous ulcers all did well, so did lupus erythematosus and those diseases of the skin associated with anaemia and debility. He was disappointed with the results in psoriasis and varicose ulcers. The radiations acted partly on the general system, partly as a stimulant to certain ulcers, and partly by reduction of pus-tension. Dr O'Donovan (London) described the origin of the light department at the London Hospital, where since May 1st, 1900, 2,800 cases of lupus had been treated. He laid great stress on the necessity of continual and continuous treatment and strict supervision of the patient's life. He thought that every type of lupus was curable except where there was lymphatic obstruction of the part affected. Up to the present there was no evidence that carcinoma ever developed on the supple skin left after light treatment. Psoriasis was very seldom benefited, but prurigo, multiple subcutaneous abscesses in children, and septic complications of wounds and fractures did well.

Dr J. G. Tomkinson (Glasgow) testified to the value of ultra-violet radiations in lupus and cutaneous tuberculosis.

Dr Gilchrist (Baltimore) mentioned the measurement of the dosage of ultra-violet light by means of lithopline, and

attempts to desensitize to light by means of small doses. Diathermy was the best treatment of lupus. Sir Norman Walker (Edinburgh) had cured psoriasis in many cases. Dr H. MacCormac (London) welcomed Dr Dore's moderate claims for light therapy. Dr W. Mitchell (Bradford) preferred diathermy to any other treatment for lupus. Dr A. C. Roxburgh (London) reminded the Section of the use of ultra-violet light with Wood's glass as a method of diagnosing ringworm of the scalp by causing fluorescence of infected hairs.

The discussion was continued by Dr R. Aitken (Edinburgh), Dr Haldim-Davis (London), Dr F. D. Hewitt (London), Dr W. K. Russell (Newcastle), Dr W. H. Brown (Glasgow), Sir R. Bolam (Newcastle), Dr Christina Brownman (Newcastle), and the President.

##### MISCELLANEOUS PAPERS

Dr H. C. Semon (London) then read a paper on the value of kryosol in the treatment of lupus erythematosus. In a short series of cases he had obtained 22 per cent cures. The paper was discussed by Drs Gilchrist, O'Donovan, Haldim-Davis, Roxburgh, Russell, and the President. Several speakers thought the drug was of value.

Dr Dowling (London) concluded the morning with a paper on the thallium acetate treatment of ringworm of the scalp. He had had ninety cases, of which seventy-three had been successful. Drs Roxburgh and Tomkinson also spoke on the subject.

#### SECTION OF TROPICAL DISEASES

Wednesday, July 20th

##### AMOEBIc DYSENTERY

Dr ANTHONY BALFOUR, President of the Section, recalled that on the last occasion on which the Association met in Edinburgh Sir Patrick Manson announced Sir Ronald Ross's discovery of the mosquito-borne cycle of malarial transmission. Dr P. H. Manson-Bahr (London) opened the discussion on amoebic dysentery by outlining methods of treatment in the past and reviewing modern methods. In his hands a combination of emetine bismuth iodide by the mouth and yodin by the rectum had proved the most satisfactory treatment of the disease. By means of the epidiascope he demonstrated a series of water-colour paintings illustrating the sigmoidoscopic appearances of this disease. Dr J. Gordon Thomson (London) indicated how, by means of samples obtained by sigmoidoscopy, the laboratory worker and clinician could assist one another. Professor C. A. Kofoid (California) described an amoeba parasite in man, which he believed to be distinct from *Entamoeba histolytica*. He showed lantern slides illustrating the distinctive features. Dr Winters (Calcutta) referred to the treatment of dysentery by stovaine, and Dr Manson-Bahr briefly replied.

##### PROBLEMS OF MALARIA PROPHELYSIS

The discussion on the prophylaxis of malaria was opened by Lieut-Colonel S. P. Jones (London), who based his remarks on the recommendations of the Malaria Commission of the League of Nations, which were specially directed towards malaria control in Europe, in places where only limited expenditure was possible. Colonel L. D. W. Greg (Edinburgh) described his experience with eighteen cases of intentionally induced malaria, and showed lantern slides illustrating the results of infection. Dr L. W. Hackett (Rome) gave an account of the mosquito destruction work of the International Health Board in Italy, where Paris green had entirely displaced oil as a larvicidal agent. He described the way in which it was applied. Dr E. Martin (Hamburg) referred to his study of malaria in South Russia and Angola, and emphasized his belief that attacks of "spring malaria" were really relapses of infection contracted the autumn before. Dr P. H. Manson-Bahr described the mode of employment of plasmodium in treatment and referred to its possibilities as a preventive. Dr D. Bohm (Prague) gave an account of the conditions under which malaria prevailed in Czechoslovakia, laying stress on its association with bad

housing, and a low standard of life. Colonel S. P. James replied that his experimental work confirmed Dr. Martini's view of the significance of "spring malarial."

### SECTION OF FORENSIC MEDICINE

Thursday, July 21st

#### ALCOHOL AND THE MOTORIST

A discussion on alcohol and the motorist which has been very generally reported in the newspaper was opened by Dr. Coaffrey Carter (Sheffield), who said that the word "drunk" was unfortunate, and gave rise to much legal wrangling. The association of congested conjunctivae with quickness of the pulse and smell of alcohol in the breath was very suggestive. In his opinion any person with demonstrable signs of alcoholic indulgence was unfit to drive a car, and therefore "drunk" without the meaning of the Act. He outlined recent work in Sheffield on the estimation of alcohol in the urine, as described in this *Journal* last year (vol. 1, p. 463). Thirty drops of urine was a sufficient amount to enable the quantity present to be estimated. Dr. F. Bogen (U.S.A.) said that the amount of alcohol in the breath could be ascertained, and bore a constant relation to the amount of alcohol in the blood. Dr. Morrison (Birmingham) said that renal disease might prove a fallacy in urino examinations, in his opinion the important factor in estimating the degree of drunkenness was the general appearance of the accused. Dr. Wilson (Glasgow) thought the accused should always be warned as to the object of the examination. Lord Russell discussed the question from the legal point of view. Professor MacFall (Liverpool) laid stress on inco-ordination of muscular movement as a test.

#### TEACHING OF FORENSIC MEDICINE

A discussion on the teaching of forensic medicine was opened by Professor Glaxter, who defined the lines on which the student should be taught. Any medical practitioner might find himself called to give skilled evidence in a court of law to assist the court in arriving at a decision. Much of the teaching of forensic medicine depended on the practical experience of the teacher, students derived much benefit from attending a court of law during a trial, as it enabled them to appreciate the surroundings and the conduct of witnesses. Professor MacFall (Liverpool) thought the course should come as late as possible in the curriculum, and that there should be provision for post-graduate teaching. Professor Sidney Smith (Cairo) described the procedure in Egypt and expressed the opinion that great economy would result from a State medico-legal service.

### SECTION OF TUBERCULOSIS

Friday, July 22nd

#### RADIOLOGICAL DIAGNOSIS OF INTRA-THORACIC TUBERCULOSIS

OPENING A discussion on radiology and the diagnosis of intra-thoracic tuberculosis from the point of view of the specialist and the practitioner, Mr. H. Morrison Davies (N. Wales) emphasized the importance of radiology as an adjunct to diagnosis in its differential aspects and its relation to the true position and anatomical extent of the lesion. He pleaded for the greater employment of x-rays in the early and doubtful case and in the following up of the so-called "hilum case." Dr. F. Rist (Paris) said that the real function of radiology was to check, correct and control. He hoped that in the near future radiological examination would not be considered as outside the term "clinical examination." Dr. J. Logan Stewart (Manchester) said he had found x-rays most valuable in the investigation of contacts. Dr. J. M. Woodburn Morrison (Edinburgh) drew attention to the danger of too much reliance on pictures and pleaded for a combination of radiologist and clinician. The discussion was continued by Dr. C. P. Lapage (Manchester) and Dr. Parsons (Ceylon).

#### PATHOLOGY OF THE TUBERCULOSIS OF CHILDHOOD

Professor E. L. Opie (Washington) who opened this discussion, said that just as examinations of persons dead

of cases other than tuberculous often gave important information about tubercles, excised lung examined by film and compared with post-mortem findings and the radiograms taken while the patient was alive were not giving the clue to the best use of x-rays as an aid in diagnosis of the disease in early life. He showed the relation of hilar glands and peripheral primary lesion and pleaded for the use in contacts of the tuberculin test and efficient radiography. Dr. R. G. Cant (London) followed, and showed many interesting diagrams of the relation of glandular infection to primary foci. Dr. Aimard-Dehille (Paris) said that the best method of interpretation of x-rays was to compare lung section from the organ, hardened in a position as near as possible to that assumed in life during the radiological examination with the plates taken at intervals during the patient's illness. He showed many sections and the corresponding x-ray findings.

#### NON-PULMONARY TUBERCULOSIS

The interrelation of the physician and surgeon in regard to non-pulmonary tuberculosis was considered by Dr. D. A. Powell (Cardiff), who said that true co-operation lay in each taking his own responsibility—the physician the diagnosis and the choice of the surgeon—the latter determining the technique. The physician could still learn more from the surgeon on the methods of immobilization. True co-operation would mean that diagnosis would be followed by action, to the more immediate and lasting benefit of the patient. Professor J. Fraser (Edinburgh) thought that the present-day treatment of tuberculosis might be summed up in excision, rest, and increased general resistance, but that hope for the future lay in obtaining the assistance of the public by education and co-operation in after treatment rather than in the combination in one of the physician and surgeon—the expert in each branch ought to come together. Dr. G. H. Girdlestone (Oxford) supported this view and said that, while a combination might be possible, it was very difficult in adult cases where highly trained specialists was a necessity. He believed it almost impossible to develop a surgical hospital in a sanatorium.

Demonstrations of sections and x-rays were given in the afternoon, and were followed by an excursion to Southfields Sanatorium.

### SECTION OF VENEREAL DISEASES

Friday, July 22nd

#### THE CEREBRO-SPINAL FLUID IN SYPHILIS

Mr. C. H. Mills (London) opening this discussion, emphasized the importance of routine examination of the cerebro-spinal fluid both before during and after treatment. Examination of the cerebro-spinal fluid about six weeks after the cessation of the initial course of treatment should prevent entirely the subsequent development of meningeal relapses and their sequelae. In every case tested at the end of the first, second, third and fifth years. All patients with a persistent positive blood Wassermann reaction should have the cerebro-spinal fluid examined no matter at what stage of the infection the patient first came under observation. If the cerebro-spinal fluid was found to be affected in a syphilitic case the patient must have treatment and periodic re-examination for the rest of life. No patient with a history of syphilis should be allowed to marry without an examination of the cerebro-spinal fluid. Dr. G. Riddoch (London) said a value could be placed upon a positive result obtained only after the initial six weeks course. Did it mean that the patient was a praetor? In any case such a patient should be treated for life. He did not think that with a praetor in whom the cerebro-spinal fluid became subsequently negative was safe even after five years. It was possible he developed without any change in the cerebro-spinal fluid. Lumbar puncture might be followed by a more distressing headache which would deter the patient from a second examination, hence all possible precautions should be used to keep the operation painless and to avoid unpleasant sequelae. Dr. D. K. Henderson (Glasgow) said that the early diagnosis of parenchymatous neuro-syphilis was

impossible, since the pathological changes were always far more advanced than the clinical signs. No patient who had had general paresis, even if apparently cured, should be allowed to take a position of responsibility. Dr J G Greenfield (London) described various tests for the cerebro-spinal fluid. He said that a patient in whom a positive Wassermann reaction persisted in the cerebro-spinal fluid after three months' treatment was almost certainly a general paralytic. Colonel L W Harrison (London) recommended that in the treatment of syphilis arsenic should be combined with other metals such as mercury or bismuth. There were many more relapses and crises of neuro-syphilis in patients treated with arsenic alone than when combined with mercury. Mr Vogo (Edinburgh) described a test which he had worked out in conjunction with Dr Keimack in which hypochlorite was used and which depended on the presence of protamine in the cerebro-spinal fluid. Dr Fremont Smith (Boston, U.S.A.) said that lumbar puncture could be made painless. The President took a more optimistic view of the treatment of neuro-syphilis than some speakers, and showed a series of cases illustrating the results of treatment, principally with trypanamide. The discussion was continued by Dr Sandeman (Aberdeen) and Dr Margaret Roiko (London).

#### TREATMENT OF GONORRHOEA

Major E C Lambkin, R.A.M.C., read a paper in which Major Lyn Dimond, R.A.M.C., had collaborated, on a gonococcal vaccine which was exclusively composed of polar (or Babes's) bodies. The existence of these had been previously known, but Major Dimond had now found that when the gonococcus was grown on a medium rich in animal nucleo-protein they were produced in large numbers, and could be separated from the gonococci to which they were only loosely attached by washing off the culture with preferably human serum, or 2 per cent saline, and centrifuging the emulsion; the polar bodies were then found in the supernatant fluid. The technical difficulties were considerable. The vaccine so obtained was employed by injecting intramuscularly, and also subcutaneously under the skin of the penis, the preliminary results had been extremely encouraging. Some cases of gonorrhoea had been cured by a single injection within three days, even when subjected to the strongest provocative tests employed to wake up a possibly latent infection, in other cases general all-round improvement had been obtained, and the relapse rate in cases discharged as cured was lower than it had ever been. In addition to the gonococcus, it had been found that all other organisms so far examined were capable of producing polar bodies when suitably cultivated, and it appeared probable that vaccines containing these polar bodies were far more efficacious than others. Colonel L W Harrison (London) said that he had been able to confirm the clinical results of using this vaccine in gonorrhoea.

#### BISMUTH IN THE TREATMENT OF SYPHILIS

The President, opening a discussion on the value of bismuth in the treatment of syphilis, said that the time had not yet arrived to assess its end-results, though arsenic was undoubtedly much more deadly for the spirochaete than bismuth. It was almost impossible to find spirochaetes in lesions after a single dose of arsenobenzol, while active organisms capable of infecting could be found in excised glands after repeated doses of bismuth. Nevertheless, the clinical results of bismuth in late cases were amazing, and very nearly as rapid as arsenic, but it was not so potent in early cases. It was most valuable in cases which had been treated with novarsenobenzol and had relapsed, it was also extremely useful in cases hypersensitive to arsenic, which, fortunately, were never also hypersensitive to bismuth. Bismuth occasionally caused dermatitis, and he had seen it in one case cause a recrudescence of dermatitis originally due to arsenic. It was a remarkable thing that, although bismuth was a strong cardio-vascular poison to animals, it caused no ill effects to the liver or kidneys in man, and could be used in nephritic patients. Whether the combination of arsenic and bismuth was preferable to arsenic and mercury was somewhat doubtful, personally he thought the bismuth combination slightly superior, and it had the advantage

that it could be given for long periods with less disturbance than mercury, even if the technique of mercurial administration was good. But it was not to be regarded as a substitute for arsenic, and it was not justifiable to give bismuth alone to early cases. Dr J C Buckley (Nottingham) considered bismuth second only to arsenic in importance in the treatment of syphilis, and a long way in front of mercury. He thought that the combined treatment, properly administered, ought to be followed by nearly 100 per cent of cures in reasonably early cases. In only one type of case had he found mercury more effective than bismuth—namely, in interstitial keratitis. He gave 0.2 gram only, a very small dose according to some authorities. He asked whether the blue line which so often appeared on the gums called for the cessation of bismuth treatment. Dr Mary Menicoll (Edinburgh) said she realized more and more the value of bismuth as an adjunct to arsenic in treatment. She had found it useful both in acquired and congenital cases in reducing a persistent positive Wassermann reaction. Dr E T Burke (Manchester) agreed that bismuth was nearly as potent as arsenic, and far more so than mercury. He had discarded mercury in his clinic for the last two years except for cases resistant to bismuth. He used it, not instead of, but alternately, with arsenic. But in cardio-vascular syphilis he thought it safer to use bismuth only, and he preferred metallic bismuth suspended in glucose. Dr W R Snodgrass (Glasgow) said that bismuth was most helpful in cardio-vascular syphilis, neuro-syphilis, and debilitated individuals generally. Colonel L W Harrison (London) referred to the work of Collard and Evers, who formed a deposit of bismuth in the ear of rabbits which, so long as it was intact, prevented the development of a chancre, as soon as it was excised the chancre appeared. Bismuth was particularly useful in myocarditis, often in combination with small doses of sulfarsenol. Certain toxic effects, such as rheumatic pains and occasional dermatitis, might follow its use. Dr Stopford Trylor (Liverpool) and Dr William Brown (Glasgow) also spoke.

#### SECTION OF RADIOLOGY

Wednesday, July 20th

#### DIAGNOSIS OF INTRA-THORACIC GROWTH

At the Section of Radiology, under the presidency of Dr J M Woodburn Morrison (Edinburgh), a discussion on x-rays in the diagnosis of intra-thoracic growth was opened by Dr Stanley Melville, who pleaded for early diagnosis in view of the fact that certain benign tumours tended to produce pressure effects and to become malignant. He urged the importance of inducing an artificial pneumothorax for diagnosis and, as a preliminary to surgical measures, in reducing pleural shock to a minimum. Mr C Thurstan Holland (Liverpool) said that, while it was easy to demonstrate by radiography various growths in the chest, then differential diagnosis was often extremely difficult and sometimes impossible. Very many intra-thoracic cases were not diagnosable by x-rays only, and the co-operation of the clinician and the pathologist was necessary. Dr A E Barclay (Manchester), Lord Dawson of Penn, and Sir Humphry Rolleston emphasized the importance of the clinician and the pathologist working together, and were followed by Dr Campbell Suttie (Glasgow) and Dr L A Rowden (Leeds).

#### TREATMENT OF CARCINOMA OF THE BREAST

Dr N S Finzi (London), opening the second discussion, said that treatment by radium needles was most effective in cases of breast carcinoma which were not too advanced. Palliation and prolongation of life were the rule, cure the exception. Radium seemed to give better results than x-rays, but delay in commencing treatment was regrettably common. Dr J H Douglas Webster (London) said that it was no longer true that the only chance for a patient with cancer of the breast was early operation. By radiological methods alone results in cancer of the breast were now being obtained by some radiologists similar to those already attained by radiation in uterine cancer—namely, a certain percentage of inoperable cases cured, while in the

operable group the results were rather better than those of surgical treatment. Professor M. J. P. Hives (Dublin) showed tables illustrating in 53 unselected cases the time and sites of recurrence. He also emphasized the necessity of knowing the histology of the cases treated. Dr A. T. Bruch (Manchester) had found the immediate results of radiation treatment good, but the ultimate results less satisfactory. If x-ray applications were started within three weeks after operation there seemed to be a far smaller number of recurrences than when treatment was delayed longer. Dr W. M. Levitt (London) gave an account of some histological examinations in cases which had received intensive irradiation. Dr R. E. Roberts (Liverpool) had found that patients who had received lead injections responded better to x-ray treatment perhaps because of an intense secondary radiation. The President thought it desirable from the point of view of duration of life to comprise not only cases which had been submitted to different methods of treatment but those which had received no treatment at all.

## SECTION OF HISTORY OF MEDICINE

Friday July 22nd

### EVOLUTION OF DISEASE

The President Dr J. D. Comrie, called attention to the fact that this was the first occasion on which a Section of the History of Medicine had been held at a British Medical Association Meeting. Sir Humphry Rolleston Bt. opened a discussion on 'The historic evolution of disease.' Beginning with clinical variations in disease from the historical point of view, he said that the surest, though a much limited means of getting reliable knowledge as to the nature of disease in the past was through morbid anatomy which had been cultivated under the name of palæo-pathology. Thus showed, for example that arterio-sclerosis, tuberculous disease of bone, mastoid disease, rheumatoid arthritis, gout, talipes, prostrhea, appendicular adhesions and rhondrophasia, among other diseases, had been well known in ancient Egypt several thousand years ago. Information was also to be obtained from the available pictures of antiquity. From pictures in Egyptian tombs rhondriophasia was known 5000 years ago. Rickets was shown in the pictures of Pompeii and Herculaneum the adenoid faces could be seen in a portrait in the Uffizi Gallery at Florence and the dancing mania of the fourteenth and fifteenth centuries had been drawn by Pierie Breughel, so that it could be identified with major hysteria. Paintings showing the buboes of the plague, leprosy, hydrophobia, and many other diseases were also available. The written records of acute diseases were more numerous but at the same time more difficult to utilize than representations by the plastic artist. Alterations in the methods of description and in nomenclature interfered with the identification of bygone epidemics. The question of change of type in disease was one of great importance in medical history. Alteration of clinical manifestation might depend upon secondary infections as in the case of the severe epidemics of influenza and in the case of bird attacks of small pox, which apparently depended for their virulence upon recombining streptococcal infections. New diseases also crystallized out from old description. Thus typhoid, paratyphoid, and typhus fevers had all been separated in the course of time from the old "continued fever" and the same applied to the various forms of remittent. War and its attendant circumstances might so alter conditions as to lead to the appearance of new forms of disease such as trench fever, trench nephritis and epidemic jaundice. The clinical recognition of diseases now distinct was often difficult in a historical sense. Tuberculosis had been identified in the Egyptian mummies. From written records there was evidence that pulmonary tuberculosis was very prevalent in ancient Greece. Whooping cough was accurately isolated in ancient Greece and bubonic plague was a disease of established antiquity. On the other hand the nature of the plague of Athens was disputed and had been thought by various authorities to be malignant scarlet fever, small pox or typhus. The pestilence in Persia noted by Cullen was supposed by Crivell to be more

than one disease throughout the fifteen years of its duration. Malaria had been prevalent in Greece from the fourth century B.C. but the history of diphtheria exemplified the difficulty of distinguishing between acute infections of the throat and identifying them with the now recognized as quite distinct. It had been contended, indeed by Adams that diphtheria arose as the result of a transformation under special circumstances of a harmless diphtheroid organism into a virulent pathogenic bacillus. In conclusion the opener of the discussion drew attention to well known changes which had taken place in the incidence of appendicitis and of neuritis.

The discussion was continued by Dr G. Mathie on Cullen (Edinburgh) in a paper entitled 'World epidemics and their relationship in cause and effect to social conditions.' He traced particularly the wide reaching effects on the destinies of the human race that had been produced by the three great epidemics of plague. Mrs M. C. Burr (Reading) contributed a paper on 'The effect of early industrialism upon the health of the community.' She showed that the conversion of the population of Great Britain from an agricultural to an industrial one about the middle of the eighteenth century had been followed by a diminution in the death rate and a considerable decrease in sickness. Diseases like rickets and scurvy had previously been rare on account of the fact that vegetables and root crops were insufficient to supply the needs of the population and that animals were slaughtered in great numbers every autumn to provide salted food during the winter. With the collection of people in the towns vegetables had been produced for market instead of merely for immediate consumption. Changes in sanitation and in the comfort of living had occurred at the same time, and work in the newly established factories of the late eighteenth century was much more healthy, however bad the factories than work in small private dwellings which were used at the same time as living place, sleeping place, and workroom. Professor van Leeuwen (Amsterdam), Dr Ritchie (Birmingham), Dr Stephenson (Edinburgh), Dr Warden (Cannes), Sir St. Clair Thom (London) and Dr Wright (London) also took part in the discussion.

Independent papers were read on 'The historical aspect of quackery' by Professor A. J. Clark (Edinburgh) and on 'The methods of introduction of drugs' by Professor W. J. Dilling (Liverpool).

## SECTION OF MEDICAL SOCIOLOGY

Friday July 22nd

### VOLUNTARY HOSPITALS AND MUNICIPALITIES

The President Dr F. N. Kay-Menzies alluded to the lamented death of Dr Cruickshank, one of the vice-presidents of the Section. Mr Herbert L. Laing then read a paper on the future relation of municipalities to the voluntary hospitals of the country. Emphasizing the fundamental importance of medical education in every respect of treatment for the community, Mr Laing made the striking proposal that in any extension of State or municipal hospital service the voluntary teaching hospital should have the predominant share in the hospital administration. If and when the Poor Law infirmaries became municipal hospitals they should be managed by the teaching hospital of the area as a mother hospital on lines similar to those on which venereal disease clinics were administered. The mother hospital would supply the medical and surgical staffs; the hospital would be subject to inspection by officials of the municipality; there might be representation of the municipality on the hospital board; and the municipality would foot the bill. In this way a great deal of disorder would be avoided and an attractive opportunity for research and freedom of thought would be maintained. Mr M. A. Parnard, chief executive officer of a County Parish Council, approached the matter from the point of view of the treatment of the patient and without reference to medical education. He described four Poor Law hospitals and said that each had a rich efficient staff, a large municipal and voluntary hospital could work hand in hand. But he envisaged the creation of a hospital service for the whole country under which though much charity

would die up, the cost would fall more equitably on those able to pay. He remarked that where institutional accommodation was provided it invariably brought with it an increased demand. Sir Henry Keith advocated small hospitals with the use of motor transport, and desired that voluntary hospitals should be left unimpeded by the restrictions of public authorities. Dr Kinloch (Aberdeen) thought that the method of management of hospitals was not important to the medical profession. Dr Brackenbury urged the claims of the general practitioner for the proper treatment of his patients. Sir Norman Walker thought that co-operation—for which he would like another word—would solve all difficulties. Dr Drummond Shells believed that all medical services would ultimately be included under State or municipal administration. Dr Macgregor felt that Mr. Erson's governing body would be unable to visualize the whole needs of the city. Dr Stella Churchill considered that the difficulties raised about municipal control were illusory, and Dr Marquell protested against chronic or menial patients being sent back to their homes too soon by Poor Law hospitals which posed as municipal general hospitals.

## Reviews.

### THE GENETICS OF SEXUALITY

THE Cambridge University Press has recently started a series of works on comparative physiology. The first and second volumes have been issued simultaneously, and we are here concerned with the second. It is entitled *The Genetics of Sexuality in Animals*,<sup>1</sup> and is by Dr F. A. E. Crew. It provides a very clear and not too lengthy account of the mechanism of sex-determination and sex-differentiation, and of the physiological processes involved. Genetics has, he considers, been too long engaged in discussing the ratios between classes of related individuals which appear in successive generations of an experiment starting with two types differing in respect of one or more heritable characters. Important as the collection and interpretation of ratios undoubtedly is, it must be confessed that to the reader who is not deeply versed in the science of genetics a shifting of the standpoint towards the physiological aspect of the subject imparts an interest that was lacking before, and we are conscious of this increased interest in reading Dr Crew's book.

The explanation of the process by which sex is determined is a problem of more than general interest, its study has led scientists into an analysis of the structure of the cell which, in its wonderful results, is in some degree comparable to the analysis of the atom in physics. Not only have the chromosomes concerned in the determination of sex been identified, but some progress has been made in unravelling their minute structure and the functions of their constituent units. It is now known that the impress of sex is discernible not only in the ova and spermatozoa, but also in every cell of the body, and that that inequality of the sexes which is so distasteful to a certain type of political theorist, is prefigured in the unfertilized germinal elements even before the individual can be said to have started on his or her career. It appears that both kinds of germinal cell, male and female, contain an equal amount of chromosome-substance, but that whereas in the female cell the substance is, in normal circumstances, of one kind only, namely X, part of this is in the male replaced by a different substance, Y, if the amount of X is above a certain limit the cell is female, if below, it is male, and observations have proved that if to a cell of male constitution an additional quantity of X is added, femaleness will result. Development however, cannot take place without fertilization, and in this process it is imperative that the sex-difference shall remain intact and also desirable, under a monogamous dispensation, that the sexes shall be numerically equal. This is effected in the following way. The chromosomes concerned in sex are

arranged in pairs, XX in the female, XY in the male, during fertilization the unfertilized ovum exchanges one of its X-chromosomes for a chromosome from the sperm—the assumption of an X producing in XX fertilized ovum or female, of a Y in XY fertilized ovum or male, and as the chances are even, males and females will be numerically equal in the long run. It is obvious, therefore that sex is determined at the moment of fertilization, and that attempts to modify the sex of the foetus by such measures as feeding the mother on various chemical substances can be expected to lead at best to the production of pseudo-haemaphroditic monsters. A good deal of this is explained, with diagrams which help to make it clear, in Dr Crew's British Medical Association lecture, which was published in our issue of August 14th 1926, p. 285.

The problem of sex-differentiation differs from that of sex-determination. At a certain stage of development there exists no gross distinction in the conformation of the male and female, but subsequently a transformation occurs and the respective external genitalia, genital glands, accessory passages, and secondary sexual characters make their appearance in orderly succession. This differentiation is, according to Dr Crew, dependent on the sex-impress inherent in every cell of the body, reinforced by a sex-hormone elaborated by the sexual glands.

The truth of the above theories of the physiology of sex is put to the test in explaining the nature of the numerous sexual anomalies which are met with in the animal kingdom, and this forms a large part of Dr Crew's very interesting book.

### MEDICAL PRACTICE ITS OPPORTUNITIES AND RESPONSIBILITIES

Certain recent experiences in the courts and relating to the administration of the Lunacy Acts have, in a somewhat startling fashion, impressed on members of the medical profession some of the acute responsibilities which the law may require at their hands. From the particular instance attention may well pass to the general situation, and hence a volume on *The Conduct of Medical Practice*,<sup>2</sup> by the Editor of the *Lancet*, is far from unhappy in the moment of its arrival. As director of an important medical journal he has many opportunities both of judging policy and of affording advice to individuals. He is therefore equipped by experience alike in the discussion of principles and in the application of these to actual events. Yet though the book is happy in its hour, we are not sure that its title is quite so fortunate. Its real theme is the conduct of the practitioner as this is or may be affected by legal or other claims, whereas the chosen phrase suggests rather a pathway to mundane success. Possibly the point is unimportant, and in any event the author and his colleagues have certainly produced a book which cannot fail to be of service to many members of the profession and to prevent, if carefully studied, many anxieties and embarrassments.

That counsel of the order provided in this volume is needed is evident when the special position of the medical practitioner is considered. Like his fellow citizens, he has his general civic responsibilities, and comes under the legal doctrine that ignorance of the law is no excuse for a breach of the law. This burden is increased by a number of special statutes which prescribe for the practitioner duties and responsibilities in relation to the courts of justice, to various public bodies, to administrative records, and to other specific obligations, as well as to the individual patients immediately under his care. Even here, however, the list is not exhausted. In addition, there is the internal or domestic discipline of the profession as this is determined in part by the General Medical Council, in part by the rules of the various licensing bodies, and in part by established custom, order, and habit. Thus the claims are numerous and varied, and many of them are not wanting in complexity, and the opportunities for blunders and mistakes are correspondingly abundant. Mere goodwill and excellent intentions are not enough. He who

<sup>1</sup> *The Genetics of Sexuality in Animals*. By F. A. E. Crew, M.D., D.Sc. 110 Cambridge Comparative Physiology. London: Cambridge University Press, 1927. (Demy 8vo pp. x + 183, 37 figs., 10s. 6d. net.)

<sup>2</sup> *The Conduct of Medical Practice*. By the Editor of the *Lancet* and expert collaborators. London: The *Lancet*, 1927. (Demy 8vo pp. xv + 332, 10s. 6d. net.)

would travel safely must know the risks and dangers of the road.

The book is certainly comprehensive, and indeed may be described as complete. Practical business and high doctrine are both fairly presented. Thus severe details of methodical bookkeeping and the demands of the tax collector are here, as are also the delicate questions which arise in connexion with the secrecy of professional confidences, the arrangements of partnerships and the responsibilities due to colleagues. Chapters on the Dangerous Drugs Act and the National Insurance Act illustrate the increasing pressure of law upon medical practice, and there is no finality, for even during the present month a new Births and Deaths Registration Act has altered the practitioner's duties in certain important respects. Even our senior readers therefore cannot afford to indulge a little folding of the hands to sleep, and the fortunate juniors, whether they realize it or not, need particularly to mark and to learn the counsels and information which the book before us supplies. For any member of the profession entering on practice whether as an assistant or a locum tenens or a partner or a principal, here are lessons and guidance which may save him many mistakes and anxieties and prove a very present help in time of trouble. We may suggest one criticism—namely, that our brethren north of the Tweed will be likely to consider that the positions created by the special characters of Scots law receive inadequate recognition.

There are still two features of the book that particularly attract our sympathy. One is the reiterated advice to every medical man and woman to become a member of one or other of the medical defence societies. Again and again, and in spite of warnings and exhortations, practitioners are to be found entangled in perplexities and responsible for heavy legal charges when under the expert guidance open to members of a defence organization their troubles would either never have happened or would have been easily and peacefully resolved. Members of the profession are not ungenerous to colleagues who by misadventure fall under legal and financial penalties, but appeals of this order are hard to justify when, by prudence and a small annual subscription, every practitioner can secure his own position.

A further welcome note in the book is a fairly sustained effort to show throughout that the customs and claims of medicine are founded, not on a narrow professional prejudice or selfishness, but on the broad basis of public interest. The community generally, and apparently in increasing measure, cultivates a critical attitude towards medicine and medical practitioners and it is well that not editors alone but the individual doctor should be prepared to show that both the domestic rules of the profession and its external policies are framed in the interests alike of the common health and of the individual patient. The editor and his colleagues have kept this sound doctrine well in view, and for this we owe them thanks.

#### THE AIR FORCE MEDICAL MANUAL

An official publication that is of more than usual interest is the *Manual for Medical Officers of the Royal Air Force*, the first edition of which was issued recently. It consists of two parts. The first contains administrative instructions regarding general organization and duties of the medical service, medical examinations and records and returns and medical stores, and a detailed account of the measures required for the control of communicable diseases. The medical examinations entail precise records of facts and assessment of the disabilities attributable to air service. Injuries contracted during games and physical recreations organized by, or with the approval of, the Air Force authority are regarded as directly attributable to conditions of service and are assessed as such. The section on communicable diseases is full. It is, however, open to criticism of the extent to which measures of control by prophylactic and therapeutic inoculations are carried, especially in such diseases as scarlet fever, measles, and whooping-cough the same thing may be said also of

the section on dysentery as the measures recommended are still in an experimental and tentative stage. Practically every channel of communicable disease is detailed. There are tables showing the periods of incubation and segregation, and in separate columns the medium by which a disease is spread the specific disease is communicated through each medium, the measures for detecting carriers, for dealing with each case as it occurs and for the protection of attendants on the sick. This exhaustive section includes also instructions on vaccination and inoculations, and on collecting and dispatching material for chemical and bacteriological examination. Each individual member of the Royal Air Force would appear to be liable to thorough bacteriological examination, not only when he is actually suffering from an illness but also when he has been in contact with a sick person or is suspected of being a carrier. Among other provisions for dealing with carriers a nominal roll of persons employed must be hung up on the door of a cookhouse or canteen and each individual certified to be free from dysentery, typhoid, cholera and undulant fever germs. A re-examination must be made every three months, and a fresh certificate signed. It is further required that carriers shall be segregated, and in the case of suspected syphilitic sores, bacteriological and Wassermann tests are to be repeated, even though on two or three successive occasions the result has been negative. Points such as these indicate the thoroughness of the instructions for the prevention of disease in the Air Force. Some twenty diseases not notified under the Public Health Acts, must be notified by its medical officers. Prophylactic inoculations for several of them must be made annually or before the season when disease such as cholera or plague is approaching. Contacts and carriers are under control, and it is laid down that men with herpes zoster are to be regarded as carriers of chicken pox, here the compilers of the manual lay themselves open to criticism.

Part II is of more special interest, as it deals with the measures for examining and assessing the physical and psychological condition of airmen, and especially the tests for the organs of special sense and for muscle balance and power of co-ordinated movement. Efficiency is determined by marks given in connexion with the various tests. One of the tests very fully detailed, is that for heterophoria with the Bishop Harman diaphragm instrument by means of it the pilot's power of landing safely is determined. In flying each pilot is rightly regarded as an individual requiring special study. The medical officer is therefore told that his best work can be done in the mess, on the aerodrome, or at games. There is an excellent chapter on high altitude flying and administration of oxygen.

On the whole this is a manual which imparts to the reader who is not in the Air Force with the extent and variety of the special attainments and qualifications required by medical officers of that branch or the service, and by the amount of laboratory investigations which they are called upon to undertake.

#### SEGREGATION AND AUTOGAMY IN BACTERIA

In *Segregation and Autogamy in Bacteria* Steward brings forward evidence which he considers shows that the lower bacteria pass through a life-cycle with alternating phases of asexual and sexual (autogamic) reproduction. After a short summary of the previous literature on variation in bacteria the writer's numerous experiments on coliform and allied bacteria are described. Briefly his view of the life-history of such a bacterium is as follows: "It is placed in new surroundings with sufficient food it multiplies quickly by simple fission (colony formation). This vegetative phase is stopped by an intrinsic force, but it can be either lengthened or shortened by external conditions (amount of food available, moisture, crowding) and it can be continued indefinitely by frequent change of surroundings."

Shortly before vegetative growth stops the second phase of the life-cycle begins, in which a few out of the great number of bacteria in a colony (either on solid or in liquid

nidus) go through segregation, autogamic conjugation, and, in certain circumstances, variation. In spore-bearing races the zygote forms the spore. Segregation in bacteria is the same as in higher forms; in it allelomorphic couples of the organism divide. We know little about the mechanism of autogamy, but it seems not unlikely that before segregation takes place each allelomorphic couple is represented in the 'anterior' and 'posterior' halves of the bacterium (Schindium and Dobell's pre-sporing division), and that, after segregation, and if nothing disturbs them, the 'right-hand' allelomorphs of one half of the body unite with the 'left-hand' allelomorphs of the other. At least this is as good a mental picture as any other. But, if a definite external stimulus is at the moment being on a heterozygous bacterium, then in the one pair (anterior and posterior) of allelomorphic couples which is concerned with the stimulus, the dominant allelomorphs are dissipated (as primitive polar bodies) the recessives come together, and the bacterium divides.

"The recessive so formed may also vary in simple fission if one of its recessive allelomorphs is not pure but is loaded with a fragment of the dominant factor. It may then vary in two directions—by increasing, or decreasing, this fragment."

### GUY'S HOSPITAL REPORTS

THE second quarterly number of this year's volume of the *Guy's Hospital Reports* contains eleven articles dealing with medical, surgical, and pathological subjects of great interest. In his full paper, recently read in abstract before the Odontological Section of the Royal Society of Medicine, on the relationship of oral infection to diseases of the skin, Dr H. W. Buber considers the diseases directly or indirectly caused by oral sepsis under seven heads, and, after insisting on the importance of studying the metabolism, diet, and environment of patients with chronic infections and of discovering the factors which reduce the resistance to the infecting organism, points out that a dramatic and complete recovery is unfortunately rare after removal of an obvious focus, is secondary and inaccessible foci are often present. Mr C. R. E. Freezer describes extensive cutaneous metastases in a case of latent carcinoma of the caudal end of the stomach, in which a remarkable power of producing scar tissue round the metastases was shown, so that a biopsy of a cutaneous nodule presented the microscopic appearances of a keloid. The extremely rare occurrence of acute suppurative gastritis is shown by the absence of this condition in the post-mortem records of Guy's Hospital during the last thirty years, and fully justifies the record of an example by Mr D. C. M. Ffles, who summarizes the literature. Dr B. G. Scholefield, Commonwealth Fund Fellow, describes experiments tending to show that the symptoms of acute intestinal obstruction are due to a soluble toxin absorbed through the portal system; he gives a critical review of the various methods of treatment. A case of subacute yellow atrophy of the liver after excessive doses of atrophin is recorded by Dr G. W. Rike, who also contributes an interesting paper on the pathology of rechaux of the cardia. Dr J. M. H. Campbell gives a detailed account of observations on the pulse rate after exercise in health and in heart disease. The clinical syndrome of intracranial meningism, described four years ago in these Reports by Dr C. P. Symonds, is illustrated by the report of a case of a probably congenital intracranial meningism in a boy, aged 18 years, associated with spontaneous subarachnoid haemorrhage; the patient was still alive at the time Dr Maurice Shaw wrote this article. Peritoneal sympathetomy is discussed by Mr J. G. Schlesinger, and Mr Philip Turner records with skilful analysis a case of fracture of the patella wired by the late Sir Henry Howe thirty-eight years ago. Dr W. I. Watt and Mr J. F. Custer Braine of the deep-sea department analyse the cases of leukaemia admitted to the hospital during the last twenty-six years with the object of assessing the value of the various methods of treatment.

*Guy's Hospital Reports*, vol. 77 (vol. 7 Fourth series) No. 2, April, 1927. Edited by Arthur F. Hurst, M.D., and W. H. Ogilvie, M.Ch. London: The Lancet Limited (Med. 8vo pp. 127-252, 27 figures. Annual subscription £2 2s; single numbers 12s. 6d. net.)

### NOTES ON BOOKS

STRUMPFEL's popular textbook of pathology and therapeutics, in two volumes, reached its twenty-fifth edition last year. It was soon exhausted, and a new edition of the first volume has again been revised by Professor CARL SEIFARTH. The opportunity has been taken to add some further details and illustrations, including a short reference to the Schick test. The absence of an index in this volume is regrettable.

A second edition of *Examination of Children*, by Dr A. LEVINSON, first published in 1924, has now appeared. While certain of the methods of examination have been expanded, the criticism previously made in our columns of the brevity of some of the descriptions and tests still holds good as an index of various kinds of clinical procedures the book is however of definite value.

Mr ROY CALVERT's book betrays its bias, first in Lord Buckmaster's introduction and secondly, in the very beginning of Chapter I. This is not a serious attempt to assess the value of capital punishment as a deterrent by a calm and reasoned consideration of the evidence, but, assuming from the beginning that capital punishment is wise, it is useless as a deterrent, it seeks to support this thesis by all available means. Most thinking persons are agreed that the present law, which makes no difference between the deliberate secret poisoner for gun who watches day by day the sufferings of his or her victim unmoved and pitiless on the one hand, and on the other the man who, goaded by provocation to fury, strikes down his enemy in a sudden rage, is unjust. Few will deny that there should be degrees of the crime of murder, and that there should be a punishment fitting to each degree. But not a few cultured and candid persons will admit that the reasonable certainty of the death penalty would not be the determining consideration to men's minds in deciding between committing and non-committing of a deliberate homicide. There seems to be a grotesque disproportion in the minds of certain persons between the value of the lives of cruel murderers and of those who go down to the sea in ships up into the air, or on roads and railways for the use and comfort of those gentlemen who sit at home at ease and shudder at the thought of the assassin perishing by the sword or noose or electric chair.

In a little volume entitled *ABC of Jung's Psychology*, Miss JOAN CORRIE aims to place before the educated layman the principal psychological views of Dr Jung of Zurich in simple and untechnical language, his own published works being, for the most part, as the writer observes in her preface, too abstruse for the general reader who is not a psychologist. The book contains four chapters: the first concerns "mind and its structure", the second, "mind and its functions", the third, "mind and its disturbances", and the fourth, "the significance of dreams". The second chapter includes a brief but clear account of Jung's 'psychological types'. The writer set herself a difficult task and has carried it out well.

"A Layman and his Wife" seem to have spent much of their time in constructing new or transforming old houses. They record their judgements on comfort, convenience and the saving of labour, in construction and fittings in their little book *Planning a Home*. They give floorplans for a 'well-end nest', a 'sunshine cottage', a 'house with angle bay', and a 'two mind house'. The subject is treated under the headings: aspect and site, roofs, walls, floors, windows and doors, with chapters on lighting, heating and plumbing. The authors are both forcible and witty. They think that the man who converts most of his small garden into a "ducky little fenced garden" will throw bricks at it in a year's time. They would reject a site where the water is contaminated by sewage, because through carelessness, ignorance, or haste unboiled water would probably be used sooner or later. They are very partial to flat roofs, but whether these are really suitable for the English climate, and how far they can be made to fit in appropriately with local scenery is perhaps doubtful.

SATURDAY, JULY 30TH, 1927

## THE EDINBURGH MEETING

THE ninety-fifth Annual Meeting of the British Medical Association ended on Saturday last, and all who visited Edinburgh for it can congratulate themselves upon having taken part in a great event in the history of our Association. Many circumstances combined to make it a brilliant success. The proceedings began auspiciously at a time when our Patron the King, and Her Majesty the Queen were on a State visit to Holyrood and the wonderful Scottish National War Memorial in the Castle was being opened by the Prince of Wales. The meeting coincided also with the celebration in Edinburgh of the centenary of Lister's birth, under the presidency of the Earl of Balfour, Chancellor of the University. But without such happy concomitants this medical congress in the Scottish capital was bound to be a memorable occasion. Edinburgh is the home of one of the world's great schools of medicine; for centuries it has bred a line of teachers and workers whose names are part of medical history, and it is regarded with loyal affection by all members of our profession, at home and abroad who have been trained within its walls. Moreover, the office of President is now held, at the unanimous wish of his colleagues in the city and district, by one of Edinburgh's most distinguished sons who, when the British Medical Association last met there twenty-nine years ago undertook the exacting duties of local general secretary. The high organizing ability, the kindly tact and discretion displayed by Dr R. W. Philip in 1898 have ripened if that were possible, in the intervening years, and this splendid gathering in 1927 will always be associated with Sir Robert Philip as its central figure and leading spirit. One thing further must be said of the Edinburgh Annual Meeting in general. To the beauty of its setting was added a most generous welcome from the Edinburgh Branch of the Association and its President, Dr John Stevens, from the University and from the city authorities, and no praise can be too high for the staff work of the indefatigable honorary local secretary, Dr Fergus Hewat, the local treasurer, Mr Alexander Miles, the deputy local secretary Mr Frank Jardine and the Scottish Medical Secretary, Dr J. R. Drever—to name only a few among the many who have earned our gratitude.

As had been foretold, the meeting was a very large one, the numbers far surpassing those of any year except 1910 when the Association last met in London. During the week 2,375 members registered but this figure takes no account of the many wives and daughters who also enjoyed Edinburgh's hospitality. Notwithstanding the large number of Sections, and all the temptations to play truant in and around the city, the attendance at the scientific and clinical proceedings was very good indeed, and, so far as an onlooker could judge from brief visits paid here and there, every speaker had an attentive audience, the debates went with a swing, and even the highest lecture theatres of the new University building could scarcely hold all who wanted to join in the work of the leading Sections. Credit for this success must be given to those who picked the subjects and opening

speakers and kept in hand the business of debate. We cannot attempt to sum up now the value of the work done in the twenty-one Sections but as will be gathered from the preliminary notes appearing this week and next in the Journal, and as the full reports will presently reveal much useful interchange of experience and opinion took place on matters of great importance to doctor and patient and to the public as well. The Pathological Museum was admirably planned and set out, and of the many interesting demonstrations arranged by the Museum Committee one at least must be noted here—the cinematograph film of living tissue growth shown and explained to full houses by Dr P. G. Canti.

Among those who took part in the scientific work were many distinguished colleagues from Canada, the United States, and the Continent, and their contributions lent an international air to the proceedings. Combined discussions such as proved so popular at Bath and Nottingham, were held again last week, each aspect of a topic common to two Sections being opened by some prominent worker. These joint debates not only help the expert to keep up with recent advances in neighbouring fields but attract the general practitioner who at one time long ago was inclined, so it has been said, to look upon the Annual Meeting as little more than an occasion for squabbles and oratory with a picnic at the end. A new Section, fittingly inaugurated this year was that of the History of Medicine a subject in which its President Dr John D. Comrie has interested large numbers of Edinburgh medical students during the past eighteen years. Now that the meeting is over he may perhaps forgive us for disclosing his authorship of the series of articles on Edinburgh which have lately appeared in these columns.

Before the scientific work began four days had, as usual, been spent by the Representative Body of the Association in shaping medical policy and reviewing finance, organization, and administration. A full account of the first two days' discussions appeared in the last issue of the Supplement and our report is concluded this week. From this full and detailed record—to which the informal commentary printed in the Journal under the heading 'Annual Meeting Notes' may serve as a key—it will be seen that a long agenda of medical political business was carried through and that several matters of much importance to the profession were advanced a stage. If on the whole the temperature of the Representative Body tends to be subnormal nowadays there are still a few subjects—such as the Memorandum on Lunacy Law and the report on the work and status of public school doctors—which seem able to cause mild pyrexia. There are moments, too, when a more general warmth comes over its proceedings. Dr Brackenbury ended on July 19th his third and last year as its accomplished Chairman and the personal ties between him and his fellow workers were very evident when illness kept him out of the chair for a day and again when it became known that the Council had elected him as its Chairman. The seven years spent in that office by Sir Robert Bolam have been time of growing prosperity for the Association and in all the progress made he can truly say. His resignation never gave Sir Robert Bolam's gifts been better applied than on July 15th when he put before the Representative Body the Council's plan for future building development at headquarters.

Upon the social side of the Annual Meeting of 1927 we will not dwell at length. Everyone knows enough of the tradition of Scottish hospitality, and that the great

capit it takes pride in doing these things as they should be done. The bigger the occasion the more certain one may be that Edinburgh will do it justice. It would therefore be impertinent to praise Edinburgh for the skill and grace with which she has entertained the British Medical Association at an exceptionally busy time, with the tourist season at its height and the King and Queen in residence. We will merely say that the ceremonies, receptions, dances, excursions, and parties, both public and private, were all and more than all we expected and, in the name of every one of the thousands who enjoyed these entertainments, we offer thanks to our colleagues and their fellow citizens.

### MEDICAL CONFIDENCES

We published last week the full text of the ruling by Mr. Justice McCauley, in a divorce case at the Birmingham Assizes on July 18th, with reference to the confidential nature of information given to the medical officer by a patient at a venereal clinic. The point had been obscured by the way in which the case was reported in the daily newspapers, and in order to make the matter clear we quoted a paragraph of the second Article of the Venereal Disease Regulations, which lays it down that "all information obtained with regard to any person treated" at a venereal disease clinic "shall be regarded as confidential," and to show the intention with which the Regulation was made we quoted also the explanation given in a circular issued with the Regulations. "It is," the circular said, "essential for the success of any measures designed to deal with venereal diseases that patients should be fully assured as to the secrecy of the arrangements." Mr. Justice McCauley referred to the Regulations, and said that doctors were not in a specially privileged position because they were acting in a department under the control of the Ministry of Health through the local health committee. He held that there was nothing in the Regulations which saved a doctor from the obligation of disclosing, if ordered to do so by the court, all the information he might have of the facts he had gained while acting under the Regulations. The information was therefore produced by the surgeon in charge.

In this ruling Mr. Justice McCauley followed that of Mr. Justice Horridge in a case heard in the Divorce Court in 1921. The late Dr. John Elliott of Chester was summoned as a witness, and called on to give evidence as to a disease for which he had treated the wife of the plaintiff. Dr. Elliott attended accompanied by counsel, but the judge refused to hear counsel. Dr. Elliott, on entering the box, asked the judge to exempt him, pointing out that he and other medical men had undertaken duties at the clinic on the distinct understanding that professional secrecy as to what happened there would be observed. He quoted the paragraph in Article II of the Public Health (Venereal Disease) Regulations which we quoted last week (and again in the opening paragraph of this article). The judge, however, said that the Ministry of Health had no power affecting the jurisdiction of the courts. When Dr. Elliott said that he was thus placed in a painful position, the judge made a distinction, which Mr. Justice McCauley clearly had in mind, and said: "You are bound to observe the regulations not to disclose voluntarily the information you have obtained, but it is your duty to give information to assist the administration of justice." Dr.

Elliott observed that the medical officers of the venereal disease clinics did not undertake not to disclose voluntarily, but undertook not to disclose it all, to this the judge replied that it was not an unfair obligation on doctors to assist in the administration of justice. Dr. Elliott then gave his evidence.

As we then observed, and as we repeated last week, it would appear that until Parliament interferes the undertaking given by the Ministry of Health in the Public Health (Venereal Disease) Regulations has become of no effect. The only remedy seems to be fresh legislation, and in 1921 the Council of the British Medical Association drew the attention of the Minister of Health to the subject, and urged that the necessary legislative steps should be taken. Nothing, however, has been done, at any rate, no public step has been taken, and the public, which it nearly concerns, as well as the medical profession, have regretfully to realize that the supposed protection afforded by the Regulations is illusory. A very similar condition may arise in connexion with other administrative procedures sanctioned by the Ministry of Health under the Public Health Acts. One such case came before Lord Mersey in the Divorce Court in 1921. A firm of solicitors had approached a medical officer of health to supply particulars with regard to the notification of a stillbirth. When he declined they applied to the local council, but its public health committee refused to give any information, stating that it viewed with apprehension any departure from the usual practice of treating such notifications as confidential, and considered such a course would be against public policy. The medical officer of health was subpoenaed. Before giving evidence he stated that he was instructed by his committee to ask for the judge's ruling, pointing out that hitherto notifications under the Public Health Acts and the Births Act had been treated as confidential. Lord Mersey said there was no reason why the notification card should not be produced, that there was no instruction in the Acts to the effect that the information was confidential, and that he did not consider the production of the card would be against public policy.

Before this, we understand, the Ministry of Health had submitted the general question as to the position in law of medical secrecy to the then Lord Chancellor in connexion with the confidential entries on medical history cards under the National Insurance Act. The then Minister of Health said that the Ministry recognized that important issues were raised, but that he was advised that a person might be compelled, by means of a subpoena duces tecum, to bring any document, private or otherwise, to the court. The document itself—in this case the record card—was not evidence of the facts stated in it, if it was desired to prove them this must be done in the ordinary way—namely, by the oral evidence of the doctor himself.

In connexion with the recent Birmingham case, Dr. Vernon Davies, M.P., raised the point as it affects venereal clinics by a question to the Home Secretary in the House of Commons on July 25th (see p. 194). The Parliamentary Secretary to the Ministry said that the matter was difficult, and that the Minister proposed to give careful consideration to it. It will be a pity if it is allowed to lapse again on the ground that it is merely a question affecting professional secrecy, for it affects the good faith of the Ministry to the public. The principle by which the members of the medical profession are guided is as old as Hippocrates: one clause of the Hippocratic Oath has been translated thus: "Whatever, in connexion with

my professional practice or not in connexion with it, I see or hear, in the life of men, which ought not to be spoken of abroad I will not divulge. I am reckoning that all such should be kept secret. The principle embodied in this has been accepted by the medical profession in all countries. Mr Justice McCardie distinctly recognized it for he said that the medical profession normally was under the duty of keeping inviolate the secret knowledge that they might gain from treating their patients, and indeed might become liable to a civil action for damages if without lawful excuse the duty of confidence was broken. But the Hippocratic words do not cover all cases uncertainty being introduced by the phrase which ought not to be spoken of abroad. The legal ruling is that as the law now stands certain information must be spoken of abroad if a judge sitting in a court of law so requires. But the matter as is very obvious concerns the public, who have accepted the undertaking of the Ministry of Health that statements made to the medical officers of a venereal clinic will not be disclosed. We are advised that the only remedy the Ministry of Health has is by way of special legislation which we venture to think should deal not only with venereal clinics but with other regulations under which the same or similar questions arise. We feel confident that in Mr Neville Chamberlain's hands the matter will not be allowed again to be forgotten.

## ANNUAL MEETING NOTES

### THE REPRESENTATIVE MEETING

#### Medico-Political Business

WE conclude in the SUPPLEMENT this week our full report of the Annual Representative Meeting of the British Medical Association held in Edinburgh on July 15th, 16th, 18th and 19th. On Saturday afternoon July 16th the representatives began consideration of the Medico-political report—by far the heaviest single section of its agenda. It is worthy of remark that when on Monday evening the Chairman of the Representative Body congratulated Dr Bone upon the completion of what was in his experience a "record" period in charge of the business before the meeting, no single recommendation of the Council on this section of its Annual Report had been rejected or withdrawn, none had been substantially modified, and one point only had been referred back (by a very narrow majority) for consideration. Apart from those recommendations the motions and amendments accepted by the meeting whether from Divisions or from individual representatives, served in the main to emphasize supplement, or elucidate rather than to limit the policy laid down in the report while the discussion on those which were rejected or not submitted to a division showed the wisdom of the Medico-Political Committee in refraining from putting forward definite proposals upon those points at present. Fees and salaries were perhaps less prominent this year than has sometimes been the case though the meeting received with great satisfaction the report from the Chairman of Council of the settlement of the difficult question of adjusting the scale for medical officers of health to meet Scottish conditions. Point of importance were settled by the meeting in connexion with the responsibility of local authorities for midwifery and ante-natal work and the conditions of consultation under the puerperal privacy regulations. The suggested application of the principles governing the accepted policy of the Association as to maternity and child welfare services and the treatment of school children to the general provision of orthopaedic treatment was accepted. The policy of the Association

was adjusted to the existing conditions of administration of general anaesthetics by dentists for dental purposes, and a scale of fees laid down for anaesthetics given by medical practitioners in connexion with dental benefit under the Insurance Acts. The tone of the general discussion on these and certain minor matters made it very clear that the Representative Body no less than the Medico-Political Committee of the Association is deeply concerned so to direct the increasing volume of communal effort in the provision of health services as to safeguard and extend the scope of the basic activities of the general practitioner, and to ensure a just measure of co-operation between the family doctor the specialist, the whole-time health officer, and the general public. More particularly it emphasized the growing preoccupation of the profession with the position of the general practitioner in the development of ante-natal and midwifery services. The general debate upon the motions by Brighton on the State and medical practice, by Turbridge Wells on whole-time officers and medical practice, and by Dr Renton and Dr Paven instructing the Council to consider the Midwives Act 1913, in the interests of all concerned with ante-natal work, served to allow free expression of the general feeling on these points. The last mentioned motion leaves the Council with a mandate to constructive work of the first importance during the coming session. Apart from these propositions the attention of the meeting was chiefly engaged by the papers proposed for the development of the medical service of public schools and the standardization of the conditions of service for public school medical officers. The difficulty raised by Dr Peter Macdonald in connexion with the determination and publication of a binding policy before consultation with the governing bodies of schools was met by discussing the whole subject in committee—a procedure that calls to mind the trouble done by the National Insurance Bill. Only one point in the dental policy set out in the Council's report proved a source of any keen controversy—the question of the benefit of periodical medical inspection of the school medical officer from resident to day pupils. In committee the meeting favoured restriction of this service both in the case of the whole-time medical officer (as proposed by the Council) and in that of the part-time medical officer. On report Dr Middleton Martin secured its reference for reconsideration by the narrow majority of 24 to 23 on a recount. The Council now in a position to discuss the whole matter with the governing bodies of public schools and with the headmasters and headmistresses.

On the Supplementary Report of Council the Chairman of the Committee and Sir Richard Luce explained the results of the Association's efforts to secure the modification of the Trade Disputes Bill and the Lordlord and Tenant Bill in the interests of the profession and the point still at issue in connexion with the Registration of Nursing Homes Bill. After the lunch interval Dr Brackenbury, who had been warmly welcomed on his return to the chair that morning, suspended consideration of the Medico-Political Report to allow the Overseas Branches to be taken at the agreed time and the meeting had an opportunity of hearing the representatives of the Overseas Branches. It was natural in view of the happening of the previous year that the speakers were mainly drawn from the ranks of the South African Branch. Tribute to the value of the Association work and especially to the results of Dr Cass mission to South Africa was much appreciated. The meeting also heard with interest explanation of local conditions from representatives of Ceylon and Burma.

#### Conclusion of the Meeting

The approval of the Medico-Political Report was followed by a prolonged discussion on the Memorandum from the

Lunacy Law Committee under conditions briefly explained in this column last week. The discussion, which is fully reported in the SUPPLEMENT this week, was continued on the resumption of business at the unusually early hour of 8.30 on Tuesday morning, and left the meeting with a considerable volume of work to be completed between the opening of the Annual Exhibition in the morning and the service at St Giles's Cathedral in the afternoon. The remainder of the agenda, however, proceeded singularly little discussion, although it included several matters of importance, notably the Council's proposals in connexion with the development of Ophthalmic Benefit. It may be hoped that the decision to accept the contribution offered by the trustees of the National Insurance Defence Trust to the Medical Representation in Parliament Fund, together with the proposed concentration upon securing the election of medical representatives for University constituencies, will mark a definite advance towards the attainment of adequate representation of professional opinion in Parliament. But if so, the passive acquiescence recorded by the Representative Body to Dr Le Fleming's plea for an increase in individual contributions must be supplemented by a fuller measure of material support than it would in itself seem to foreshadow. On the Public Health and Poor Law Report, Dr Lenys-Lloyd explained the part which should, in the opinion of the Council, be taken by the Association, both centrally and within the Divisions and Branches, in the education of the public in health matters, and suggested that, to avoid the overburdening of local societies, the new work should be carried out by *ad hoc* committees with special societies. The discussor showed that the ideas underlying the resolution of the Nottingham meeting and the proposals formulated by the special sub-committee to which the matter was referred are gaining ground definitely, if slowly, within the Association. On the report on Poor Law reform Dr Brackenbury explained the way in which the new proposals, published by the Minister of Health since the completion of the Annual Report of Council, exclude that unification of local health administration which is a cardinal point in the Association's policy. He emphasized the need for securing some modification in these proposals before they are embodied in the projected bill.

The National Health Insurance and Hospitals Reports gave rise to a certain amount of discussion, but elicited little real opposition to the policy outlined by the Council. It was clear that the need of a clinic system in the development of ophthalmic benefit was fully recognized, alike by ophthalmic surgeons and by the Representative Body at large, and that the meeting was content to leave to the Council the elaboration of a scheme embodying the requisite safeguards. The discussion on hospital policy showed that the period of general education in the policy of the Association is bearing fruit. On the one hand, there was no opposition to the proposal to impress upon visiting staffs the importance of securing satisfactory recognition of their services in accordance with the Association's policy, on the other the Chairman of the Hospitals Committee was glad to accept, on a motion from Sainsbury, the instruction to consider the formulation of a middle-class hospital policy, and the reference to consider the detailed proposals put forward by Brighton for the application of the hospital policy in the better regulation of the contributory schemes which are permeating the whole hospital system of the country. The points made by Dr Fothergill in his presentation of the motion commanded general support. For the rest, the amendment of the Council's recommendation as to the staffing of clinics and hospitals for the early treatment of mental disorders, proposed by Mr Masterman and Dr Gillespie of Belfast, was accepted by Mr South as a better expression of the real intention of the Council than the original motion. The object was not to exclude

any group of medical men from their proper sphere of work, but rather to prevent the exclusion of specially qualified private practitioners from a field of service in which their work is of value. On the Naval and Military Report Sir Richard Luce emphasized the advantages offered to entrants to the R.A.M.C. at the present time. In presenting the report on medical benevolence Dr Walker had once again to appeal for more effective support of medical charities, but on this occasion he was able to refer to signs of real progress made under the Association's scheme. The proposed reconstitution of the Charities Committee was approved. No discussion arose on the reports from Scotland, Wales, and Ireland. Dr Hugh Miller called attention specially to the development of the social side of the Association's work, made possible by the possession of its new House in Edinburgh. Sir Ewen Maclean for Wales (in the absence of Dr W. E. Thomas, Chairman of the Welsh Committee) and Dr J. Mills for Ireland both emphasized the great value of the help received from Dr Cox in all local difficulties. The meeting closed with the usual votes of thanks.

#### THE PATHOLOGICAL MUSEUM

The organizers, no less than the exhibitors, are to be congratulated on the arrangement of the demonstrations in the Pathological Museum. The grouping of the exhibits according to particular departments in medicine, and the appointment of one authority responsible for each, contributed greatly to the success, and the large hall of the Anatomy Department, in which the demonstrations were assembled, was ideal for the purpose. It would be impossible in a short notice to detail all the interesting exhibits, and invidious to select for special mention any one, seeing that the level was so uniformly high and so varied in its appeal that one would have to be an expert in many departments of medicine to appreciate everything thoroughly. The writer of this note, therefore, can only state what appealed to him most, pleading his ignorance of the other groups so beautifully illustrated. Quite interesting, though not emphasized in the official programme, were the large-scale histological illustrations of pathological conditions—the work, it is presumed, of Mr Richard Munro—which gave one the clue to the success of the Edinburgh methods in the teaching of students, and the beautiful wax models of skin diseases and syphilitic conditions from two separate departments of the University confirmed that impression. Of special interest was the excellent series of specimens of gall bladders removed at operation, showing single cholesterol stones causing mucocele or empyema, mixed gall stones with various pathological conditions, and chronic cholecystitis of different grades, all shown by Professor D. P. D. Wilkie. A very instructive exhibit, arranged by Mr J. N. Hentley, demonstrated many pathological conditions of the thyroid gland. Some rare inflammatory states—such as tuberculosis, syphilis, and Riedel's thyroiditis—which present great difficulties in diagnosis, were illustrated. Simple goitres, parenchymatous, colloid, cystic, and nodular goitres, together with lingual and mediastinal tumours, formed an interesting group. The two types of toxic goitre—the exophthalmic and the toxic adenoma—and the various simple and malignant neoplasms, were also included. Professor John Fraser demonstrated large sections of the mammary gland in various normal conditions, in the resting stage and as affected by the menstrual function, as well as studies of the gland in malignant disease, showing the routes of lymphatic dissemination within the organ, and several uncommon varieties. One of these, showing cancerous formations in the wall of a large cyst which had existed for forty years, was of peculiar interest, in that it suggested that the irritation of the contents had produced the neoplastic response. It is almost ungracious to point out that this

excellent demonstration was missed by the inclusion of a diffuse eucnemoma of the breast which was wrongly labelled as a hyperplasia in a virgin breast due to menstruation and by the prominence given to a very common histological type which was said to be a rare comedone variety. In the histological section, under the charge of Professor T. J. Mackie, there was an interesting exhibit showing the whole range of spirochetal infection. The demonstration of the renal circulation in the human subject, in the foetus, and in childhood, and in various animals, given by Mr. D. M. Morrison attracted much attention. To obtain these specimens the torts had been injected with coloured celluloid dissolved in acetone, and when this material had set the soft tissues were macerated away by means of hydrochloric acid leaving the beautiful rhorescent vessels. Dr. James Davison showed a series of specimens illustrating different types of diseases of the liver, especially atrophic cirrhosis and acute and subacute yellow atrophy. Along with these were specimens of liver necrosis and cirrhosis produced experimentally in rabbits by means of coal tar. Very striking too, were the paraffin sections of whole lungs in children, illustrating the processes of lobar pneumonia, bronchopneumonia, emphysema gangrene, pyemia and tuberculosis. Altogether the Pathological Museum was one of the best and most complete exhibitions of recent years.

#### A NEUROLOGICAL CONFERENCE

SOMETHING like an international conference of English-speaking neurologists is taking place in London this week. It is composed of members of the American Neurological Association and the Section of Neurology of the Royal Society of Medicine. It was opened on the evening of Monday, July 25th when the members attending the conference were received by Sir James Berry (President of the Society) and Lady Berry. During the evening Sir James Purves-Stewart, President of the Section of Neurology, gave a lantern lecture describing a visit which he had paid to the holy mountain of Athos, situated on one of the three prongs of the Chalcidice Peninsula projecting into the Aegean Sea. The district is famous for its monasteries and hermitages, founded and maintained by various nations belonging to the Eastern Church, some of them of great antiquity. From this monastic republic women are banished and the ban even extends to animals of the female sex so that there are no cows for milk or hens for eggs, but from his own experience Sir James Purves-Stewart unguined that female insects were exempted! He gave a nice account of five days spent on the peninsula, during which, travelling along lonely mountain tracks or through dense forest, he contrived to visit thirteen out of the twenty monasteries. He found them rich in objects of devotion but extremely primitive in hygienic and refectory arrangements as did Curzon, who visited some of them in 1837, bought as many illuminated manuscript as he could, and related his travels in a most fascinating book, *Travels to the Monasteries in the Icarus*. The largest of the monasteries Sir James Purves-Stewart reached was founded in 661 in its palm days it had 500 monks but has now only 140. Each monastery lives its own independent existence, not fraternizing with the others, though to some extent in competition with them, especially over the possession of sacred relics. At one monastery was the mummified left forearm of St. John Chrysostom, while at other monasteries were his sacrum, his tibia, and one of his tarsal bones. The mummified right forearm of St. Andrew the Apostle, his tibia, his humerus and the lower end of one femur were all under different guardianship. Then there was the ulnar bone of the woman of the well in Samaria, the right hand of the mother of the Virgin Mary, the lower jaw of John the

Baptist, the lower jaw of St. Luke, the tibia of Zarlana and the skull of St. Basil. Other relics, some of them reputed to be wonder-working, were the wood of the true cross, fragments of the red robe of Pontius Pilate, and various icons, said to have been painted by supernatural hand. Of the real artistic treasures on the peninsula the most noteworthy was a thirteenth century paten cut from a single plate. The rank and file of the monks appeared to be of subnormal intelligence, they belonged mainly to the peasant class, most of them were illiterate, their dull eyes flashed no religious fire, their waking hours were mostly occupied in the recital of prayers or in rest and contemplation in their cell. They had no intellectual or social life, and their only labour was to tend a few olive trees. They looked flabby and pale-faced as in an occasional day's work would do them good. In the sick compounds the principal trouble was senile decay in their old age, and some were also suffering from dyspepsia and malaria, or from pulmonary or joint tuberculosis unrecognized or untreated. The impression he took away from the whole peninsula was of oppressive silence and mental stagnation. Some of the monks said and thought the great majority of monks sat! After the lecture the company adjourned to the library for music and refreshments. The serious business of the conference began on the following day, the morning and afternoon of which were occupied in the reading and discussion of short papers. On Wednesday there was a debate on the cerebellum and on Thursday on encephaloid disorders in organic disease of the nervous system. These we hope to report, along with the Hughlings Jackson Lecture by Dr. Charles L. Dana in our next issue.

#### WEST LONDON POST GRADUATE COLLEGE.

THE statement recently made in the House of Commons by the Minister of Health describing a plan for making the West London the hospital of a post-graduate medical school lends special interest to the arrangements now and for a good many years existing at the West London Post-Graduate College. The hospital was founded in the year 1856 and incorporated by Royal Charter in 1894. It is situated on an island site 3½ acres in extent, the present front of the hospital is at one end of the area which extends backwards from the main road for a considerable distance. During the last fifteen years the hospital has acquired the freeholds of all the houses on this site. The present hospital contains 226 beds but its extension to provide between 400 and 500 beds is in contemplation. The calls made by the population surrounding district on the limited accommodation of the present hospital are very numerous, and beyond its present resources. With the exception of St. Mary's Hospital, which lies to the north, it is the only general hospital west of the district served by St. George's Hospital and there is now nearly a mile of London to the west of Hyde Park Corner as there is east of that point, the town has been growing westward at a great rate. The West London Hospital is easily accessible there are a tube station and two Metropolitan stations within half a minute's walk and omnibuses to all parts of London pass the door. Post-graduate instruction has been carried on continuously at the West London Hospital since 1895 and many thousands of medical men from all parts of the world have attended the classes and demonstrations there. The West London was the first hospital in London where the practice of the hospital was reserved strictly for qualified practitioners—men at first, but now women also. It is claimed that the Post-Graduate College was the earliest institution of the kind to be attached to a general hospital. The first dead and moving spirit at its inception was the late Mr. L. A. Bidwell. Under existing arrangements any qualified practitioner can attend the hospital practice for a week, a

month, three months, or a year, commencing at any time, but the teaching is divided into three sessions—October to Christmas, January to Easter, May to the end of July. At other times practitioners attend the ordinary hospital practice, but no special classes or demonstrations are given. Medical men in practice in the district can take out annual tickets at a reduced rate. Post-graduates are appointed to clinical assistantships in the various departments for periods of three or six months. These appointments are made by the house committee of the hospital on the recommendation of the college committee. There are four clinical assistants in the department of anaesthetics, who administer anaesthetics personally under the supervision of the honorary anaesthetists. It has always been the aim of the Post Graduate College to give continuous instruction for graduates according to a definite weekly syllabus rather than to arrange intensive fortnightly courses, special courses can, however, always be obtained provided not less than six graduates intimate to the dean that it is their wish for such special instruction. A reading room and smoking room are provided.

### CONTROL OF SCARLET FEVER

A REPORT recently issued by the Ministry of Health on some administrative aspects of scarlet fever consists, as its subtitle sets out, of a report on current English public health practice in the control and treatment of scarlet fever. It has been prepared by Dr Allan C Parsons with the assistance of a committee of medical officers of the Ministry of Health, from material mainly furnished by medical officers of health and superintendents of isolation hospitals. While the main object of the inquiry was to collect facts and figures relating to certain administrative methods employed by various local authorities for the control of scarlet fever, the personal opinions of the various medical officers of health and superintendents were invited on particular points. The facts, figures, and opinions are first set forth at length and summarized, and the conclusions of the officers of the Ministry of Health are given subsequently. The customary length of detention of scarlet fever patients in hospital and the effect of a longer or shorter retention on the occurrence of return cases or complications was one of the subjects discussed. The conclusion was that there is no good reason for prescribing a routine period of detention of more than four weeks in uncomplicated cases, while in others the period should be based upon the patient's general clinical condition. Although the number of scarlet fever patients who require the benefit of hospital treatment is held to form a very small part of those attacked, a very large proportion of the cases, especially in London and the larger cities, are at the present time removed to isolation hospitals. On this point the view expressed is that the right of admission should be restricted to severe cases and to those occurring in houses where other members of the family are engaged in milk-selling, clothes-making, and so on, or where there are several susceptible children. It is considered that, generally speaking, a close investigation of home conditions would probably show that more patients could be treated at home without harm to the public, their families, or themselves than is at present the practice. As to the question of terminal disinfection, Sir George Newman, in his preface, states that a large amount of popular "disinfection" is not only entirely inefficient, but wasteful and absurd. A comparison of the results as indicated by the percentage of secondary cases in towns and districts where traditional methods of disinfection are in vogue with those of towns and districts where they have been dropped or materially modified shows that there is not much difference. Other

questions discussed in this interesting report are the circumstances which govern the policy of removal of scarlet fever patients to hospital, the employment of otologists on the staff of fever hospitals, the value of the Milne treatment, and the bacteriology of scarlet fever.

### GIFT OF AN INSTITUTE OF BIOCHEMISTRY TO THE MIDDLESEX HOSPITAL

A WIDE vision and wise judgement, in conjunction with generous philanthropy, were shown by Mr S A Courtauld when he gave £40,000 to the Middlesex Hospital for an Institute of Biochemistry, which is to be named after him. By this gift Mr Courtauld has shown his keen appreciation of the great part science plays in practical medicine. Although it is only in quite recent years that the term "biochemistry" has become familiar, yet it is not a new science. The end of the eighteenth century was marked by Lavoisier's researches on the chemistry of respiration. Even earlier than this Willis made the illuminating discovery, by chemical examination, that sugar was present in the urine of the diabetic patient. The discovery of the microscope allowed the gap between plants and animals to be bridged. Minute organisms were found to be the causes of fermentation, putrefaction, suppuration, and many infective diseases. In the nineteenth century the famous researches of Dr Richard Bright showed the relation between the blood and the urine in kidney complaints. Sir Alfred Garrod proved by biochemical study that gout is associated with excess of uric acid in the blood. In more recent years chemical methods have been applied to many physiological problems, and some of the great discoveries biochemistry has given us have already passed into the routine of medical practice. Nevertheless, it was not until 1912 that analysis of the blood was made use of in clinical medicine, but since then the chemical pathologist has rendered valuable help to the clinician. Professor E C Dodds has informed us that in the year 1921 87 specimens were sent to the biochemistry department from the hospital for a report, in 1925 the number was 12,457. This great increase in the work of the department has been handicapped by lack of space. The new Institute of Biochemistry now founded will therefore be heartily welcomed by all officers of the hospital, and also by scientific investigators everywhere. The institute will work in conjunction with the hospital on the one hand, and with the Bland-Sutton Institute of Pathology on the other. The proceedings at the ceremony at the Middlesex Hospital on July 26th, when Mr Courtauld laid the foundation stone, were opened by H R H Prince Arthur of Connaught, chairman of the board of governors, who, after welcoming the visitors, expressed the gratitude of all concerned to Mr Courtauld for his wise and liberal gift. Sir John Bland-Sutton then gave an address on biochemistry in relation to medicine, in which he outlined the meaning and growth of this department of science, and concluded by expressing the hope that a discovery might one day be made within the walls of that laboratory which would make the world gape with astonishment. Mr Courtauld then inserted in the cavity prepared in the foundation stone a glass vessel containing, among other things, certain preparations of internal secretions made by processes devised in the Department of Biochemistry of the Bland Sutton Institute of Pathology. Mr Courtauld then proceeded to lay the stone, having first been presented with a replica of an ancient Greek Roman spatula by the architect, Mr Albert W Hall, and with a fifteenth century Italian bronze pestle and mortar by a representative of the builders, Messrs Holland and Hannen and Cubitts. A vote of thanks to Mr Courtauld, proposed by Mr S G Asher, chairman of the council of the Medical School, and seconded by Mr A E Webb-Johnson, the honorary

treasurer, was enthusiastically earned. The Institute of Biochemistry is to be a five-floored building containing laboratories fully equipped with all requirements.

### THE GOLD COAST

THE Gold Coast owes its name to the joy with which early explorers detected grains of gold mixed with the sand of the rivers. Its prosperity is now due to the trade in cocoa. In 1925 it furnished nearly half the world's supply of cocoa, and if the adjacent territory of Nigeria is included fully half. The next large exporters are Brazil, Ecuador, and San Thome. The name "Gold Coast" is now generally understood to mean the British Colony, which includes a vast territory in tropic Africa much larger than was indicated by the fringe of red marked on the maps of the last century, for it embraces the Gold Coast proper, Ashanti, the Northern Territories, and the British Mandated Territory of Togoland. The Governor, Sir F. G. Guggisberg, has recently issued a review of the events on the Gold Coast from 1920 to 1926, together with a forecast for the years 1927 and 1928. It gives a picture of an active administration, in close touch with the natives, the planters, and traders. The political organization of the country is described, as is the manner in which the native chiefs are supported in their authority, and serve to inform the colonial administration of the course of events. The chiefs are the popular representatives in a country where there is no place for plebeians. Large expenditure has been incurred to encourage trade, two fine harbours have been built, railways laid, and roads cut and their surfaces treated with tar. Water supplies have been established, with water rates in towns and tickets for water in the country. There are telephones and telegraphs, the former being the more used in a country where many of the minor officials are illiterate. But of most interest to us is the growth of measures for the public health. The old makeshift hospital barn with its leaking roof is gone, and there is now a really efficient headquarters of medicine and surgery, and one that has been so planned as to be capable of "indefinite expansion." Sufficient land has been obtained for the construction of the future medical school, with all the necessary accommodation for students, not omitting recreation grounds. In reckoning the accommodation needed the authorities have looked far ahead and proposed that this medical school shall serve all the British West African colonies. A scheme has been drafted and is now under the consideration of the Secretary of State. It is hoped to secure a full medical training for African medical students, besides continuing to furnish junior African medical officers, and also to train nurses and midwives. Some indication of the need is shown by the death rate of infants in the colony, which in some places is over 400 per 1,000 births. Note is made of a difficulty that arose out of the appointment of a fully qualified native doctor to the charge of a township where lived some twenty Europeans. The desired that the local doctor should be a European, and a question was asked in the British Parliament. The position has not been changed and the Governor defends it on the ground that there is a white doctor in the next town thirty miles away on the railway. The medical staff of the colony numbers sixty even, and three of them are natives. The number of cases of tuberculosis which come to light is increasing annually, but steps are being taken which it is hoped may prevent further spread. A start has been made in the treatment of leprosy by the formation of a lepers' camp on a small scale. The death rate of the European officials has fallen from 20.6 per 1,000 in 1903 to 12.8 in 1924, while during the same

period the invaliding rate has fallen from 65.1 to 21.7 per 1,000. The colony produces, not gold, but cocoa. The Governor declares the first aim of the Government's agricultural policy to be "the protection, improvement, and development of our staple product—cocoa."

### GRENFELL OF LABRADOR

THE KING has conferred the K.C.M.G. upon Dr. William Thomson Grenfell in recognition of his medical missionary work for thirty-five years in Newfoundland and on the Labrador coast. The announcement of this was made by the Governor of Newfoundland on July 25th, at the ceremonial opening of the new Grenfell Hospital at St. Anthony, Northern Newfoundland, which has recently been erected at a cost of £30,000. Sir William Grenfell, who was born in 1865, received his medical education at Oxford and the London Hospital, where he was house-surgeon to Sir Frederick Tierce. Since the commencement of his work in connexion with the Mission to Deep Sea Fishermen in Labrador in 1892, he has brought about the building of four large hospitals, seven cottage hospitals, two orphanages, four public schools, and numerous other institutions. He has also raised an endowment fund of £200,000 for the maintenance of the work. During the war he came to Europe and served with the Harvard Surgical Unit. While in this country it occurred to him that his experience gained in Labrador and North Newfoundland as to clothing in hard weather would be of value to the British army, and he wrote for this JOURNAL a paper, illustrated by drawings on clothing against cold, which was published in our issue of January 15th 1916 (p. 26). Sir William Grenfell has already received many distinctions. He was made C.M.G. in 1906, has received honorary degrees from Harvard and Toronto, and was awarded the Murchison bequest of the Royal Geographical Society in 1911. He is a Fellow of the College of Surgeons of America, as well as of the Royal College of Surgeons of England.

### THE DISPOSAL OF THE BODIES OF STILLBORN CHILDREN

WITH the coming into force of the Birth and Death Registration Act 1926 several questions have arisen with regard to the disposal of the bodies of stillborn children in particular circumstances. These circumstances are probably not of common occurrence, but when the questions do arise they are of considerable importance. It is necessary therefore to have a clear idea of what the law now requires, and to remember that not the recent Act alone, but also the Cremation Act and Regulations determine this matter. Requirements arising out of the new Act have been fully set out in an article in the JOURNAL of June 18th last (p. 1118) and in a note in the SUPPLEMENT of July 2nd. These need not be repeated in detail. It may be said, however, that every stillbirth must now be registered and that no body of a stillborn child may be buried in a burial ground "without the prior production of a registrar's certificate, or, if an inquest has been held of a coroner's order. There is no legal necessity for the production of such a certificate or order if the body be buried elsewhere than in a burial ground, and there are no restrictions on such disposal of the remains of stillborn children. It would obviously be a wise and proper precaution, however, on the part of any person so disposing of the remains, with regard to the disposal of the body of a stillborn child by cremation, the position is as follows: Section 8 (1) of the Cremation Act, 1902, and Regulation 3 of the Cremation Regulations, 1920, provide that no cremation of human remains shall take place except in a crematorium, of the opening of which notice has been given to the Home

<sup>1</sup> The Gold Coast. A Review of the Events of 1926 and the Prospects of 1927. By His Excellency the Brigadier General Sir Frederick Gordon Guggisberg, K.C.M.G. Governor etc. Accra, 1927. (Pp. 8vo pp. 347.)

Secretary and in accordance with the regulations made by him. The expression "human remains" here includes stillbirths, and such remains therefore cannot lawfully be disposed of by cremation except at places and in the manner indicated. In this case also the production of a certificate, in pursuance of Section 7 (4) of the Births and Deaths Registration Act, 1926, that the stillbirth has been duly registered is necessary before the cremation of the remains of a stillborn child can be permitted.

### THE TRAFFIC IN OPIUM AND OTHER DANGEROUS DRUGS

WE have received from the Home Office a copy of the report to the League of Nations by the British Government on the traffic in opium and other dangerous drugs for the year 1926. The report is one of a series furnished annually to the League of Nations, in accordance with a scheme of the Opium Advisory Committee of the League, which, under Article XVIII of the Treaty of Versailles, concerns itself with the traffic in dangerous drugs. This is the first occasion on which such a report has been communicated to the press. It deals mainly with the system of control of importation, exportation, manufacture, and sale of opium (raw, "prepared," and medicinal), morphine, heroin, cocaine, etc., which was instituted, at the suggestion of the British Government, under the International Opium Convention concluded at The Hague in 1912. As explained in the *BRITISH MEDICAL JOURNAL* (March 12th, p. 481, and July 16th, p. 107), the later Opium Convention concluded in February, 1925, is as yet inoperative, owing to insufficient ratification, and the Hague Convention remains the only international instrument for the control of traffic in these drugs of addiction. Reference is made in the report before us to the better control of internal traffic in these drugs in accordance with new regulations, framed in 1926 under the Dangerous Drugs Acts, whereby medical tribunals have been instituted to which the Home Secretary may refer cases of suspected illicit use, more strict measures have been taken to prevent addicts obtaining supplies from more than one doctor, and records are required to be kept by all doctors, dentists, and veterinary surgeons of purchases of dangerous drugs. Statistics are given which show that the amount of morphine and its salts manufactured in, and exported from, Great Britain was less in 1926 than it was a few years ago. Only two firms in Great Britain—both in Edinburgh—are licensed to manufacture morphine, while seven firms were, in 1926, licensed to manufacture medicinal opium. Interesting figures are given of the estimated consumption of opium, morphine, heroin (diacetyl-morphine), and cocaine in hospitals in Great Britain in 1925. They are as follows: opium 750 lb., morphine 1,149 ounces, heroin 403 ounces, and cocaine 1,669 ounces. It appears that in 1926 95,173 lb. of raw opium were imported into Great Britain from India, as against 40,885 lb. from Turkey, and that Indian opium is now the chief source from which morphine, its salts, and derivatives, are manufactured in this country, some 3,040 lb. of Indian opium were last year exported from Great Britain to the United States. The report states that "information received by His Majesty's Government during the year (1926) shows that the illicit traffic in drugs continues on a large scale." Two seizures of British-made morphine dispatched through Czechoslovakia on import certificates issued by its Government, were made in Shanghai by the Chinese postal authorities. Another seizure was made of the huge amount of 8,200 ounces of heroin at Hong-Kong in the luggage of a passenger on a steamer from Europe, dispatched from Switzerland via Marseilles. There is good ground for believing in the existence of powerful syndicates operating in Hong-Kong, Amoy, Tonkin, Shanghai, etc., in this illicit commerce. In

March, 1926, in Englishman was arrested in London in unlawful possession of twelve 1-lb. tins of cocaine, smuggled into this country from Germany. Likewise at Kingston, Jamaica, a case of opium, consigned, it was alleged, under certificate to Bluefields, Nicaragua, was confiscated. The Government of Nicaragua pronounced such importation illegal, and vouchsafed the information that the amount of opium consigned was so great that even in fifteen years it could not have been consumed for legitimate medical purposes. These extensive smuggling operations which are exposed, to say nothing of those which escape detection, serve to emphasize the urgent need there is to restrict the production of these dangerous drugs—at their source—to medical and scientific requirements only.

### PUBLICITY

SIR THOMAS HORDER has had occasion to protest in the columns of an evening paper against what he describes as a garbled account of some remarks he made during the MacAlister Lecture delivered to the newly founded London Clinical Society on July 7th. The publication drew a letter from a correspondent of the evening paper, which showed that this reader, at any rate, had misapprehended at least one opinion expressed by Sir Thomas Horder, and this seems to have led him to make his protest. We are given to understand that the officers of the society had originally invited the wives and friends of doctors to the lecture, and that a notice to this effect appeared in the lay press, though not as the result of any action of the society. At Sir Thomas Horder's request the society afterwards sent out a notice to the newspapers stating that the lecture was not open to laymen. The president of the society informs us that he is confident no lay reporter was present. His inference is that the report published in the evening paper must have been supplied by a medical man. If this conclusion be correct, we can only agree with Sir Thomas Horder in thinking this action regrettable, we must assume that the chairman took care to explain to the meeting that the lecture was not to be reported, but would be published in full in the *Lancet*, where it appeared on July 16th. Any medical man present at the lecture ought to have respected the wish of the society and of the lecturer. It would then have been open to the newspapers to quote what Sir Thomas Horder actually said, or, had they preferred a shortened version, they would have found it in our issue of July 16th (p. 107). We also think that it would have been only courteous for the evening paper to wait until it had an authorized report or abstract. It is very easy in technical matters to fall into an error of interpretation, and it could not really matter very much to the lay reader whether his newspaper gave him Sir Thomas Horder's opinion on a technical matter in one week or in the next.

WE regret to announce the death, on July 26th, of Sir H. Bryan Donkin, at the age of 82. We hope to publish a notice of his life in an early issue.

THE University of Edinburgh is about to lose two of its most distinguished professors. Professor G. Lovell Gulland has, under the age limit, retired from the office of physician to the Royal Infirmary, to which he was appointed in 1911, and has also resigned the chair of medicine, to which he was appointed in 1915. Professor James Cosser I Watt, M.D., F.R.S., who has been professor of natural history since 1882, has retired also. His numerous researches have been concerned chiefly with fish and fisheries, and with the history of the development of horses, a subject which at one time led him to investigate telegraphy.

## LISTER CENTENARY CELEBRATION AT EDINBURGH

It was held to be fitting that in the centenary year of Lord Lister's birth the meeting of the British Medical Association in Edinburgh should include the celebration of the centenary. Lister was house-surgeon at the Royal Infirmary, Edinburgh, 1854-55, lecturer on surgery, Edinburgh School of Medicine, 1855-60, assistant surgeon, Royal Infirmary, 1856-60 and Regius Professor of Clinical Surgery, University of Edinburgh, 1869-77.

The meeting was held in the McLellan Hall of the University on the evening of July 20th. The vast building up to the dim recesses of the upper gallery, was filled and it may be wondered how many heard the speeches, in spite of microphone and amplifiers. The Chairman was the Chancellor of the University, the Earl of Balfour, and the procession to the platform, headed by the university and city forces, included the most prominent figures in the academic and public life of Edinburgh as well as the President of the British Medical Association, the Chairmen of Council and of the Representative Body, and other principal officers, and distinguished guests of the Association from foreign countries and the dominions. A very large number of those present wore academic robes and the white with the bright dresses of the ladies made the spectacle one of great brilliance. A programme of organ music preceded the celebration.

### Lord Balfour's Tribute

The EARL OF BALFOUR said that it was unthinkable that the British Medical Association should meet in Edinburgh in the Lister centenary year without calling together an assembly such as this to do honour to the great surgeon. Though Lister was not born north of the Tweed, yet it was in Scotland that he matured his great discoveries, it was in two Scottish universities (Glasgow and Edinburgh) that he laid the solid foundations of his immortal fame, and to Edinburgh, both in the earlier and later part of his Scottish career, he always turned with affectionate regard. Lister was a very great man, but, like every other great man, he owed part of his greatness to the fact that at the moment at which his career began his peculiar and special gifts found their peculiar and special opportunity. That he would have been a great surgeon at any period of the world's history, that he would have added lustre to the pursuit of medicine in whatever age and land he had been born, the speaker did not doubt. But he was enabled to write his name in indelible characters upon the history of medicine in no small degree because he was a contemporary of two other great men—Simpson and Pasteur. Of his debt to Pasteur little need be said. Pasteur's position in the history of civilization was fixed and immortal. But it was impossible also to estimate the position of Lister in surgery without noting the relation of his work to Simpson's discovery of chloroform. Without the discovery of chloroform it would have been impossible to perform, even under the most perfect aseptic conditions, the operations which had added so greatly to the knowledge of disease and diminished so greatly the sufferings of mankind. On the other hand the very discovery of chloroform, the very impetus it gave to attempting operations which before that time no surgeon had dared to attempt, augmented the appalling mortality which in pre-Listerian days inevitably haunted the operation room. The two discoveries—Simpson's and Lister's—mutually assisted one another. Without anaesthetics the operations could not have been carried on, without the Listerian method the operations, though carried on, would have had with terrible frequency a fatal result. It was necessary that the dreams both of Simpson and of Lister should be fulfilled before the benefits which either of these two great ornaments of the Edinburgh school of medicine brought to mankind could be fully reaped. They had heard from high authorities lately how greatly surgical operations had increased the knowledge of the nature and the course of disease, and the method by which certain diseases could be dealt with, but surgery without anaesthetics was not the surgery which afforded such knowledge, and surgery without

aseptic treatment was too often the harbinger of death rather than the cause of health and recovery. To these great men a double debt was due. It was not merely the debt of individual patients to the skill of physician, it was the debt which all men owed for that steady accumulation of knowledge and steady growth in the art and practice of healing which had made the generation to which the speaker belonged so remarkable in the history of medicine. And it was not merely a new mode of dressing wounds for which they had to be grateful nor the discovery of an anaesthetic it was for the combination of the two. Without both the great men who co-operated in this result, the result could hardly have come about at all, each was in a sense dependent on the other.

It was a terrible page in the history of medicine, agonizing to the eyes of the helpless surgeons themselves in the era before Lister's work was established. It made one's blood run cold to learn what was happening even in the best hospitals of the capitals of Europe and America. In those days a feeling of dread took possession of every surgeon and the patient suffered from terrors based on lack of knowledge but just as vivid. In the Centenary Volume just published there was one terrible narrative which, he confessed, he could not read without emotion—namely, the description of a hospital, he thought in Vienna, where one would had so awful a reputation that women used to implore with tears that to that death trap they might not be sent. The conditions of those days were such as to make one feel that of all the benefactors of sick mankind the greatest benefactor of all must be Lister himself, who wrought deliverance. Lord Balfour confessed to some surprise that Lister's discoveries were not immediately hailed by the whole profession with the approval which was now universal. It was very easy to be wise after the event and nobody need boast the possession of such facile wisdom. But he was profoundly puzzled at the first reception of Lister's work by his colleagues. The progress of his ideas gained ground at different rates in different countries and centres of medical education, but in no place, not even Glasgow and Edinburgh, was it as quick as one would have expected in view of the general admission that the existing state of things was a scandal to the medical profession. After all, these experiments of Lister were not laboratory experiments, they were not carried on in some scarcely known centre of learning, they were not couched in unknown language, they were not taught in obscure schools. The very surgeons who refused to accept this new thing had full opportunity of seeing the effects of it and yet for some reason which to him was quite unintelligible they remained unconvinced. After all, putrefaction was a very obvious phenomenon, and if it was possible to see by walking across a passage or a courtyard putrefaction with all its horrors in one ward, while another was free, one would have supposed that such an appeal to experience would have been disregarded. But this was not the case, and he hesitated to censure any vehement condemnation of that frame of mind when he remembered that Sir James Simpson was himself one of the doubters. Of that great man he would never speak except with profound reverence. As a youngster he (Lord Balfour) had known him. Simpson did countless acts of kindness to him and to his family. He was one of the most lovable as well as one of the ablest of men. But it was strange that he who had been one of those to point out most eloquently the horrors which attended the surgery of his day should have died in 1870—certainly in the early days of the Lister regime—unconverted. He would that Simpson had survived a few years more or that to desire the impossible he could have lived until that present hour, to see how Lister's discovery along with his own would carry their names forward in a common fame to the remotest posterity.

These commemorations of great men (Lord Balfour concluded) were becoming frequent and he thought them useful. He had himself been personally concerned in at least six during the last few months—Baron, Newton, Faraday, Beethoven, Richard Bright and now Lister, a catalogue of great names. The services which these men rendered to man and could not be weighed or even compared. Yet even in that splendid catalogue the name of

Lister stood out supreme in this respect—that, by his forethought, his determination to reach a certain goal, the inspiration and genius which enabled him to grasp at once the full significance of Pasteur's discovery, he of all those famous ones had the inestimable blessing of having by his efforts immediately and directly diminished to an extent quite incommensurable the preventable sufferings of mankind. That was surely the most glorious tribute which could be paid to any man, and he rejoiced to think that Lister lived long enough to see the full value of his own work and to enjoy the grateful appreciation of his fellows.

Four short addresses followed.

DR W. WATSON CHEYNE, Bt, F.R.C.S., speaking as an old house-surgeon and assistant of Lister, perforce recapitulated to some considerable extent the tribute he paid to Lister at the memorial meeting at King's College Hospital last April. He gave a description, for the benefit of those many lay people in the audience, of the conditions which brought about putrefaction in wounds, and contrasted the picture of the pre-Listerian hospital with the hospital of to-day. He told how Pasteur's work opened the way to Lister for the solution of the mystery as to the cause of putrefaction, and sketched something of the laborious development of technique which followed. He concluded with some remarks on Lister himself and the great influence which he exercised upon his students. He always treated them with great kindness and consideration, and was ever ready to help anybody in need.

Professor TURPIN, K.B.F. (Paris), expressed his gratitude to the British Medical Association for enabling him to be present on that occasion. He was one of those who could speak from personal experience of the pre-Listerian era and afterwards, but his most cherished recollection of Lister dated back to Pasteur's jubilee celebration in the theatre of the Sorbonne, where there were assembled the leaders of science from every quarter of the globe. Never before had such a collection of great men been gathered into one group, but Lister and Pasteur stood there in the midst, the cynosure of all eyes. Everyone knew their record of achievement, and everyone saw them in wonderment and awe. He confessed that he was unable to restrain his emotion at that spectacle. Lister brought about a revolution in surgery all over the world. His discovery could be said to have affected the destiny of the human race. Before Lister he himself knew of a series of cases in which there were as many deaths as there had been amputations. It was impossible to estimate the number of lives which had been saved in consequence of this discovery. Lister in his search after truth and his service to mankind represented the highest ideals which any profession could uphold, and in making this acknowledgement and in presenting greetings and homage to the University of Edinburgh, Professor Turpin said that he spoke not only for himself but for all French surgeons.

Professor HARVEY CUSHING said that it had been given to few so to identify themselves with great benefactions to human kind that the mere mention of their names would for ever recall, not only the man, but his legacy. On a May morning a few weeks previously he had stood at the portal of the Lincoln Memorial in Washington and gazed upon the figure of the emancipator. As he read again the familiar phrases of Gettysburg there came to his mind how comparable were Lincoln and Lister. Lister freed man from the shackles of sepsis, Lincoln from those of slavery. How different were the men, their medium of service, and the manner in which the seemingly inevitable was thrust upon them. Who had made the greatest gifts to mankind, those who had left an inheritance that had supplied, like the utterances of Christ, what minds had yearned for, those who had added to man's comforts and found ways to lessen hunger and want, those like Lincoln who had freed men from bondage, or like Lister from the horrors of suppuration? One answer certainly could be made, that only when the gift required great self-denial, and only if the giver were one that walked uprightly and worked righteousness and spoke the truth in his heart, would he, like St. Francis, come to be canonized and for ever blest. When issues were critical circumstances often so combined

as to bring the right man at the right time to the right place. An individual was caught up in the vortex of a revolution in thought, and was placed unquestionably at its very centre. It was idle to speculate whether the opportunity made the man, as was perhaps true of Lincoln, or the man the opportunity, as was more apparently the case with Lister. What really mattered was that the conjunction should take place. The opportunity to do something of lasting benefit to one's fellow men doubtless lay before all, yet even if they had the imagination to realize it, they lacked the courage to grapple with it, the tenacity to hold it, and the persuasiveness and unselfishness to secure converts and disciples. Lister, horrified at the condition in which he found surgery, deliberately elected to crusade against the most evident obstacle in the way of its advance. Were he and Lincoln accidental or inevitable? Suppose they had been born fifty years earlier or later, would they have remained unknown, or was their form of genius bound to find an outlet for its expression at any time and in any place? Was it chance alone that focused the anti-slavery movement on Lincoln, or on Lister the movement to banish sepsis? Or were they both swept along as part of a greater all-embracing Will, each in his different sphere singled out by the finger of destiny for the significant role? What preparation had either of them? The one was in obscure backwoods Iowa, the very product of the soil, the other had a different background, to be sure, but he was a sensitive man, to whom strife was hateful, and yet he was surrounded by opposition and misrepresentation and compelled to make a fight for truth. Why? Simply because he had set out innocently to answer certain questions. Why does the pupil dilate? Why does the blood coagulate? Why do wounds fester? He found the answer, and felt that all others to whom human lives were entrusted must be made to believe. It was doubtful whether blind fortune could have lifted from the crowd any more practical, humane, and earnest men equally far removed from any motive of self-interest who could have filled, as Lincoln and Lister did, their difficult and lonely places. What each of them had to do had to be done largely single-handed. Faith they had, soon conviction, ere long experience, and with the sharp mordant of experience both of them faced situations without precedent, and by the aid of instruments found or devised by themselves arrived at their goal over untrodden ways. Each of them had the common sense and the flexibility of purpose not to let the real issue be submerged in the public mind through fruitless discussions about its consequences, but each was his own most severe critic, and each had the honesty to admit what there might be of truth in diverse opinion. An awkward civilian during times of great military achievement, Lincoln had left behind him the memory of grace higher than that of mere breeding. Lister was to the manner born, and survived to see a grateful world at his feet. One of these men for an ideal, the other for an idea, one by proclamation, the other by demonstration, wrought their different achievements. In beginning his peroration Professor Harvey Cushing quoted the extract from Lincoln's speech inscribed on the monument at Washington, which, he said, "put into words for a people what Lister for a profession might have said with a little change."

With malice toward none, with charity for all, with firmness in the truth as God gives us to see the truth, let us strive on to finish the work we are in to bind up the nation's wounds, to care for him who shall have borne the battle, and for his widow and his orphan—to do all which may achieve and cherish a just and lasting peace among ourselves and with all nations.

"So may our profession" (Professor Cushing continued) "reap from Lister's life something far more precious than pride in his accomplishment and the satisfaction of claiming him as our own—namely, that spiritual harvest which comes from the example of an unblemished character—for kindness, meekness, and comfort were in his tongue. Though lives die the life is not dead, and the memory of lives such as these will be reverently and forever shared not by a profession alone, not by a nation alone, but by the universal brotherhood of man."

Professor JOHN STEWART (Halifax, Nova Scotia) said that simplicity was the keynote of Lister's life and work. He was simple in his tastes, simple in his methods, simple and clear in his thinking. He loved music, especially

Scottish songs he loved children, and, what was perhaps not generally known he had a keen sense of humour. It was a delight to hear him tell a humorous story with the appropriate manner and gesture. What some thought a certain aloofness was really the shyness of a child. Many of his associates felt that there was a certain atmosphere about Lister which distinguished him. He was anything but cold. He was fond of having his students, clerks and dressers to dine with him and many of them remembered the hospitality of the host and his charming conversation. Professor Stewart recalled the occasion when he dined last with Lister. At this time the boyish heartiness had gone, a grave sweetness had taken its place. His sister-in-law—he was already a widower—was his housekeeper and the speaker was the only guest. After Miss Syme had left the table, Lister drew up his chair and they talked for nearly two hours, among other things about the then recent development of the diphtheria antitoxin, and the failure of tuberculin to fulfil what was expected of it. To the suggestion that he should write a book on the beginning and development of antiseptic surgery, Lister shook his head saying that he did not now feel equal to much work. He said, "I can say with the apostle that I desire to depart and I feel this very deeply when I think of my dear wife." While the main cause of his depression was loneliness due to the death of Lady Lister, another cause was his regret at the elaborate ritual which was replacing his own simple routine, and yet another was the want of recognition of the value of his early researches in histology, the action of the nervous system, and the nature of inflammation. Nothing in his memories of Lister impressed him more than his confidence in the continuity of life. "It is our proud office," he said once, "to tend the fleshly tabernacle of the immortal spirit," and in a letter he wrote on the death of Lady Lister he said "May you and I so live during the rest of our earthly life that we may rejoice her!"

LORD BALFOUR, in closing the meeting, announced that the prize for the best essay on the influence of Lister had been awarded to Mr. George W. Gale of Edinburgh and a second prize to Mr. Russell Love of Melbourne. He also stated that the University and the Royal Colleges had conceived the idea of erecting an institute in memory of Lister, to contain pathological and other departments, and any assistance which could be given to this great project would be gratefully acknowledged by those authorities.

### ACUTE RHEUMATISM IN CHILDREN ITS RELATION TO HEART DISEASE

THE Ministry of Health has issued this week a report on acute rheumatism in children in its relation to heart disease.<sup>1</sup> Several inquiries have recently been made into this subject, and the report should be read in connexion with that of the Medical Research Council on "Social conditions and acute rheumatism," the two reports of the special subcommittee of the Science Committee of the British Medical Association published in our SUPPLEMENTS for July 3rd, 1926 and April 16th, 1927 and Dr. Reginald Miller's notes on the several reports, which appeared in our issue of May 28th last (p. 952).

The object of the present inquiry is stated to be "to examine the advisability of further organization for the supervision treatment, and after care of children of the poorer classes, suffering or convalescent from the various manifestations of acute rheumatic infection and especially the provision for them of special institutional accommodation." The report, therefore, deals primarily with existing disease, and with preventive measures only in so far as they are directed against the sequelae of the disease, and especially the cardiac sequelae. Although our knowledge of the etiology of rheumatism is extremely vague at present, as the discussion of the bacteriology contributed to the report by Dr. Eastwood shows, several facts of fundamental

importance bearing on the policy to be adopted in dealing with the disease have been long recognized or have been brought to light by the inquiries mentioned. Thus it is known that the disease may be so insidious in the early stages as to be readily overlooked unless carefully searched for, hence the necessity for adequate routine examination, that the grave sequelae of rheumatism may in almost every case, be avoided if proper after-treatment is not neglected. Hence we are permitted to conclude that the prevention of its disastrous cardiac sequelae is a question of ways and means that rheumatism cannot be satisfactorily treated in poor homes and so, if treatment is to be successful, the children must be received into suitable institutions. Poor homes, but not the poorest, seem to be in some way generators of rheumatism, as appears to be clearly revealed in a comparison of different types of school, for it is in the public elementary schools that rheumatism abounds, whereas the private preparatory and public schools are exempt from the disease. The reform of the poor home probably involves questions of general culture, education, the standard of living, and kindred subjects, and its consideration would afford useful employment for our politicians.

#### Statistics of Heart Disease

The main inquiry embraced in the report falls under three headings: (1) the census of existing rheumatic disease, (2) the present machinery for dealing with the cases, and (3) the additional machinery required. With regard to the census, there are approximately 5,000,000 children in average attendance in public elementary schools in England and Wales. Somewhat more than one-third of these were subjected to routine medical examination in 1925, the actual total being 1,798,397 and a further 820,953 were inspected as "special cases"—that is, selected by teachers as specially needing examination. Information as to the incidence of organic heart disease in all these children is not available but in 1924 an analysis was made of the defects revealed in a large sample (598,167) examined in London and in twenty-four large districts representative of the whole of England and Wales during the course of routine examination. Of these, 4,285 (0.7 per cent) were considered to have organic heart disease, 3,251 (0.5 per cent) of them being referred for observation only, whilst 1,054 (0.2 per cent) required treatment. In addition, 1.1 per cent of the whole number examined were considered to have functional heart disease which in 0.1 per cent was severe enough to require treatment. In Scotland the corresponding percentage of organic heart disease is reckoned at 0.52, and in New York at 1 per cent. We may therefore take it that an incidence of 0.5 per cent of heart defect for which only supervision is required and 0.2 per cent of heart defect sufficiently severe to require treatment are conservative figures for the incidence of organic heart disease in children actually in attendance in ordinary elementary schools in England and Wales. The figures do not tell us what percentage of the cases are due to rheumatic infection, and it is difficult to obtain definite information on this point. Some authorities place the proportion of deaths due to heart disease which are ultimately traceable to rheumatism as high as 50 per cent of the total deaths from heart disease, a figure which Dr. Glover, who deals with this part of the subject in the report, considers to be too high. He suggests that 40 per cent is probably a safer figure in which case we must ascribe some 25,000 deaths annually to heart disease of rheumatic origin in England and Wales. In one American series of statistics rheumatism was ascertained to be the cause of the heart disease in 449 out of 1,052 cases, in another 39.8 per cent were of rheumatic origin. The statistics are in fact so affording some idea of the amount of heart disease which is, as before said, considered possible to prevent almost entirely or arrest before attaining a serious degree of severity.

#### Treatment and After-Treatment

With regard to the existing machinery for the treatment of cases of rheumatism and their after-treatment, the report takes the metropolitan district as an example, and

<sup>1</sup> Ministry of Health Reports on Public Health and Medical Subjects No. 41. London: H.M. Stationery Office or through any bookseller. 1927. Price 1/6 net.

quotes Dr Pugh's report to the Metropolitan Asylums Board for 1925:

"There are six London children's hospitals, in these the total accommodation (in 1924) was 706 beds, which received 10,096 in-patients, of whom 371, or 3.7 per cent, suffered from rheumatism or its effects. The pressure on the accommodation of voluntary hospitals is for a somewhat rapid passage of patients, and the average stay varied from 20 to 30 days. The stay of rheumatic cases is generally longer, at the Hospital for Sick Children, Great Ormond Street, it averaged 60 days in 1919-20. Some children's hospitals have their own convalescent homes and are able to transfer a small number of their rheumatic cases to them, a few cases are transferred to special country homes of limited accommodation; sometimes it is necessary to send these patients home to await vacancies. Physicians have long lamented the necessity for the premature return of rheumatic cases to their homes."

Then there are the general hospitals and the Poor Law infirmaries, which, with the six children's hospitals, are estimated to receive a total of 2,938 such in-patients annually. The children who are admitted as in-patients to these institutions are appropriately treated during the acute stages of their diseases, most of the children, however, who attend the hospitals are not ill enough, or not fortunate enough, to secure admission as in-patients, and must perforce attend as out-patients. It is this class of out-patient child which gives rise to the main part of the practical problem calling for solution, and in them, probably, is produced the main bulk of preventable rheumatic heart disease. The following statement of the Almoner of Guy's Hospital bears on this aspect of the question:

"The number of children with subacute rheumatism attending as out-patients at intervals would be difficult to ascertain. It must, however, be very large, and it would appear that these early cases should be given as much consideration as the acute cases. The children who are seriously ill are usually referred to me by the physicians with a request to provide immediate nursing treatment under skilled supervision, followed by prolonged convalescent treatment under skilled medical supervision. Few of these children can be admitted to such a hospital as this owing to the pressure on beds here, which precludes the possibility of blocking many beds with these very prolonged cases. Immediate admission to the infirmary for treatment during the acute stage, with a view to transfer when fit to a Metropolitan Asylums Board hospital such as Queen Mary's or The Downs, has seemed to us to be the best solution of the problem at present, but unfortunately experience shows that the children do not always go to the Metropolitan Asylums Board institution, and we have record of cases in which children have returned to this hospital, for perhaps the third time within a few months, with symptoms of acute rheumatism, having been nursed for short periods and then discharged to their homes. The few that are admitted to the wards here also present a problem as, being the more severe cases, transfer to a suitable institution is especially desirable as soon as the acute symptoms have subsided. Unfortunately the voluntary societies have neither the accommodation nor the funds for many such long and difficult cases."

This aspect of the problem has been investigated by Miss Horst Smith, who contributes a report on the conditions obtaining at St Thomas's Hospital during the year 1926. In the out-patient department during the year 508 children under 12 years of age attended, 22 per cent of these already had cardiac damage and in an additional 21 per cent had symptoms of threatened cardiac involvement. 34 acute cases were admitted to the wards and 14 to infirmaries or other hospitals, 68 with more chronic conditions were sent (often after considerable delay owing to long waiting lists) to special institutions or convalescent homes but no fewer than 392, or 77 per cent, many of whom would have been recommended for admission had there been any accommodation available, were treated at home. This is a favourable instance, great efforts having been made at St Thomas's to make every possible provision for these rheumatic cases. Mackenzie in 1908 laid down that the rheumatic patient should be kept strictly in bed until there is assurance that the condition is quite abated, even though six months may elapse before this result is brought about. A year before, C. A. Sutherland had recommended six months' rest in bed, or longer if necessary, followed by sanatorium treatment for one or two years. Recent opinion is in favour of substituting "graduated rest" for complete rest and so gradually allowing the child to resume carefully graduated and supervised minor activities.

The chief medical officer, in his annual report for 1913 to the Board of Education stated that "perhaps the best method of dealing with children with heart disease is to send them to a residential school for a period of prolonged treatment." Several schools of this type have been estab-

lished in recent years—namely, the Edgari Lee Home at Willesden, the Kinnaird Home in Sussex, St Mary's Home, Biondstans, and the Baskerville Residential School, Birmingham. These have to be reckoned among the existing machinery already referred to, and supply a total of 188 beds. In addition, the Metropolitan Asylums Board reserves 16 convalescent beds at Crishlinton and has recently allotted 56 beds at Highwood Hospital, Brentwood, at Downs Hospital the Board has, on an average, some 80 beds always filled with rheumatic cases.

#### Recommendations

With regard to the provision of further machinery, the best example of a scheme for the treatment of rheumatism is considered to be that in operation in Birmingham. All rheumatic children discovered in the course of routine medical inspection in the schools in that city are reported to the rheumatism bureau at the Children's Hospital as cases needing supervision or the advice of a consultant. If recently ill they are admitted to the Children's Hospital for a period which may include treatment at the Moseley Hall Convalescent Hospital for Children. When convalescence is established they are sent to the Baskerville Residential School, which has 94 beds. The subacute and chronic cases are placed on a waiting list for the Baskerville School or are referred for periodic examination by the consultant. The cases needing supervision are visited by nurses or examined by medical officers of the education authority. After discharge from Baskerville the case is reported to the school medical officer of Birmingham, and its after-care and supervision are undertaken by the nurses and medical officers of the education authority working in close touch with the "rheumatism bureau," or in special cases by the consultant himself. Supervision is continued until school-leaving age, when the medical history and disability, if any, are reported to the juvenile employment bureau.

Here is, in fact, an almost complete scheme which is linked in close and effective liaison, nominally by the rheumatism bureau, but actually by the willing and close co-operation of many persons and committees. The whole work is co-ordinated and controlled by a specialist, who is consultant to the Children's Hospital and Baskerville School and also a medical officer of the Education Committee.

## England and Wales.

### ELISOM COLLEGE

PRINCE ARTHUR OF CONNAUGHT attended the celebrations in connexion with the seventy-fourth anniversary of Founder's Day at Ipsom College on July 23rd, and opened the new sports pavilion, which has been erected at a cost of £3,000. Previous royal visits to the College were paid in 1855, when it was formally opened by the Prince Consort, in 1895, when the then Prince of Wales laid the foundation stone of the Tower School, and in 1903 by King George, who was then Prince of Wales. The new pavilion contains separate changing rooms for the home and visiting cricket and football teams, very good washing facilities, including shower baths, ample accommodation for spectators, and a well placed scoring box. Part of the building is in use as the school tuckshop. Prince Arthur was received by a guard of honour of the Officers' Training Corps, and, after members of the council had been presented to him in the library, he distributed the prizes in the Big School, which has now been remodelled in oil. The head master, Mr A. C. Powell, in his report, stated that the school now contained 350 boys, and is soon as accommodation was available the number would be increased to 400 boarders in eight houses, without a preparatory school. This contrasted sharply with the position a year ago, when only about 250 boys of public school age were in residence. Commenting upon the exceptionally good scholastic successes of the previous year, he mentioned in particular the fine achievement of E. A. Marsh in winning the senior open science scholarship at Jesus College, Cambridge, and in passing the examination for the B.Sc. Lond.

while at school at the age of 18. The award during the year of 45 school certificates would be a worthy record for an institution twice the size of Ipswich. The Officers' Training Corps had distinguished itself by winning the Surrey Schools' Shooting Cup, the College had also been placed eighteenth out of 71 public schools in the competition for the Ashington Shield. Two new entrance scholarships, one of £120 and the other of £105, had been made available by special bequest. Plans for the future included the building of a new sanatorium at an estimated cost of £50,000, and an additional five court. Prince Arthur emphasized the value of public school training in the preparation for life in the world, the combination of study and athletics enabled English boys to face hopefully the demands of all spheres of life, and especially those of the medical profession. Though medicine promised financial fortune to only a few, it provided opportunities for great and useful work. He then passed to the consideration of the possibilities opening up for successful emigration particularly to South Africa, a boy required about £1,500 to cover fully all the liabilities including his fare to that country, his special training there in agriculture, and the ultimate purchase of land, but no parent could find a better way of investing that amount of money.

#### WELSH NATIONAL SCHOOL OF MEDICINE

On July 16th (p. 112) we reported that the suggestion had been put forward that a compromise might be effected, on the lines of the system in force at University College London between those who desire to see the School of Medicine for Wales a separate college of the University and those who wish it to be a department of University College of South Wales and Monmouthshire, Cardiff. Further negotiations and discussions have taken place, and it seems to be thought probable that an arrangement may be come to. At a meeting of the Court of the University last week the matter was again discussed and was referred to the University Council to continue the negotiations.

#### THE HUMANE KILLER

It seems a pity that the Animal Defence and Antivivisection Society has not, in the past, devoted more of its energies to the introduction of humane slaughter of animals for food instead of making unprovoked attacks on medicine. Through the courtesy of the Duchess of Hamilton and Miss Lind af-Hageby, a representative attended the inauguration on July 14th of a model abattoir at Letchworth. A large number of visitors were present. The institution appears to have been built by voluntary subscription, it is proposed to turn it into a company. The Animal Defence Society will retain supervision of the methods employed, and hopes to open in London an establishment for the sale of the products of the abattoir. The inauguration began with a brief speech by the Duchess of Hamilton, followed by addresses, of which the first was by the Right Hon. Noel Buxton, formerly Minister of Agriculture, who said that there were 20,000 slaughtering places, mostly remote and obscure, in the country. The only method of advance in humane killing was to press the question on Parliament using the public health as an argument. Dr. Heiss, director of the public abattoir at Straubing, Germany, said that in Germany uncertified meat which did not come from public abattoirs was not approved for public sale. Professor Dahlstrom, of the Royal Veterinary College, Stockholm, stated that in Sweden the humane killer was always used except in the case of pigs for the English market. He did not consider that the Jewish method of slaughter could be compared with the use of the humane killer. Before the meeting the visitors inspected the premises which are very well arranged and equipped. In addition to the slaughterhouses there are cold storage accommodation, rooms for scalding and chilling, a lard room and a sausage room. It is intended to add a building for dealing with by-products. As one of the objects of the institution is to raise the mental and moral standard of the butcher, there is a lecture hall for his instruction, a neatly panelled dining room, and accommodation for change of clothes and baths.

At the close of the address the audience was given the alternative of taking tea or viewing a demonstration of the use of the humane killer. A large majority of those present, including numerous ladies, accepted the latter alternative. It happened that a party of London butchers who had come to the meeting were the first to reach the small pig slaughtering chamber. The lad organizers, however, were intent on exhibiting their methods to the foreign delegates. An altercation arose but the butchers stood their ground and ultimately proposed a truce under which they were to witness the death of the first of the three pigs. This was agreed to but the crowd seeking admission was so great that the butchers had some difficulty in extricating them else. The organization of the meeting was not good, and the employees were perhaps unaccustomed to perform their work in the presence of so large a company. But the whole installation seemed to be a praiseworthy attempt to set an example in humane slaughtering and, under the supervision of a properly qualified veterinary expert, should be a success.

#### A PENDING NURSING SCHEME

The Reading Council for Nursing Services a promoters a scheme under which societies with State insured or voluntary members can ensure nursing attendance for the sick. The report of the council for the year ending March 31st shows that nursing services were then available for 36,620 members of various societies a number which has increased since that date to 45,800. The expenses of the council are met by an annual contribution from the societies at the rate of fourpence a member. The number of visits paid by the nurses during the year was 4,851, the average cost for each visit was something less than one shilling and the total cost to each society was one and two-thirds pence a member. In the case of insured persons even this small cost was reduced by a State grant. Consequently at the end of the year's working there was a considerable balance returnable to the subscribing societies. The cost of administration was very small, being under five per cent of the total income. There is no restriction as to the area in which the nursing services can be obtained and last year one of the members received nursing services as far away as Yorkshire. The council endeavours to carry out its work through local nursing associations though it does not restrict it to these associations where such associations are not available it may make payments to hospitals or to recognized nurses called in by patients. The council also acts as the local "clearing house" for the collection of vouchers and the payment of accounts in connection with the Queen Victoria Jubilee Institute (London) scheme. The council urges the contributory societies to make the fullest possible use of its services and there seems to be no doubt that it is carrying on most valuable work with the strictest economy in administration.

#### PORT OF MANCHESTER

The medical officer of health of the port of Manchester, in his annual report for 1926 states that 177 cases of sickness came under notice during the year. There was no outbreak of cholera, plague or yellow fever either in the port or in Manchester bound ships but two cases of smallpox occurred one of which was removed to hospital at Hong-Kong and the other isolated on board. The cases of malaria numbered eight of pulmonary tuberculosis seven, of pneumonia five of enteric fever two, and of other specified infectious diseases one each. The number of rats destroyed on shipboard was 254 and on dock premises 2,655. Except in twenty ships fumigated with sulphur dioxide, the methods of destruction were trapping and poisoning. Hydrocyanic acid was not employed. Of 139 classified rats 712 were grey 57 black and 270 brown. No plague-infected rats were discovered. Of several consignments of frozen fish coming from New Zealand in January the first two had been carried in boxes on deck and ten and a half tons were condemned. Later consignments, stowed in refrigerator, arrived in good condition. Early in the year the *ss. Manchester Indica*, running into bad weather in the Atlantic and sustaining

damage to her rudder, took fifty-one days in crossing. Her full cargo of apples, of 600 tons weight became unsaleable and was condemned, being removed by rail to the sludge tip near Thelwall for disposal. Of 428 Canadian cattle which she was bringing over 176 had to be disposed of at sea.

## Ireland.

### PURE MILK SUPPLY

PROFESSOR R. J. JOHNSTON, F.R.C.S. M.P. (Queen's University, Belfast), speaking at the Unionist School at Portlough on public health, with special reference to milk supplies, described milk as a perfect food, containing everything that was necessary for human life. It was also a perfect food for bacteria and microbes, which multiplied at an appalling rate, especially when the milk was warm. The milk as sold for human consumption was full of microbes which had been introduced after the milk came from the cow. The problem, therefore, was how to preserve the milk as far as possible in the state in which it came from the cow. After mentioning various ways in which milk became infected, Professor Johnstone described several methods which the Government should adopt to secure a clean milk supply. The first thing was to take samples of the milk as supplied to the consumer. The second was to inspect the places where the milk was produced to see that the cowsheds were well ventilated. But even when the authorities had taken samples, inspected cowsheds, and tested cows, reliance had, after all, to be placed on the goodwill of the milk vendor. Apart from regulations there was a need to create in the producer a desire to keep his cowshed clean and his cows under hygienic conditions. The way in which they could create that desire was by showing him that there was money in it. Another important factor was the education of public opinion in favour of having clean and pure milk.

### TRANSFER OF MEDICAL OFFICER IN ATHLONE

By a majority of one vote the Westmeath County Health Board transferred Dr W. H. Coen from the position of medical officer of Monte dispensary district to the combined office of medical officer of Athlone No. 1 dispensary and district hospital. Under Section 5 of the Local Authorities Officers and Employment Act the local bodies, whilst they have no power to make new appointments, may transfer existing medical officers to a vacant position subject to the sanction of the Minister of Local Government and Public Health. In connexion with Dr Coen's appointment and recent sanction, Sir James Craig, M.D., questioned in the Dail the policy of the Minister. The Athlone County Board of Health, he said, had appointed a medical man who had had but two years' service to a large hospital and dispensary over the head of another candidate, who had had twelve years' experience and a distinguished university course. The late Minister had refused to sanction the appointment, but immediately the new Minister came into power sanction was given. The whole matter had caused the greatest possible dissatisfaction and anxiety amongst the medical profession in sanctioning the appointment the Minister was not carrying out the intention of the Act.

## Scotland.

### MEDICAL REFEREES

THE Scottish Board of Health has appointed Dr Alexander James Muirhead and Dr Hugh Miller to be district medical officers (medical referees) in their department. Dr Muirhead is an M.D. of Edinburgh. He has held several appointments as medical officer to local authorities and other bodies and was local medical referee for a large assurance company. During the war he served as surgeon on a number of H.M. ships, and also in naval

hospitals. He has been for several years in private and panel practice, and has had experience of statutory committees in connexion with the Insurance Acts. Dr Miller is an M.B., Ch.B. of Glasgow, and a Fellow of the Royal Society of Tropical Medicine and Hygiene. He was for a number of years deputy medical officer of the fever hospital and Poorhouse Hospital, Hamilton. During the war he was medical officer in various hospitals at home and abroad, and subsequently acted as medical referee under the Ministry of Pensions. He has also done a considerable amount of referee and medico-legal work, and is a member of various medical committees. He has been for a number of years engaged in private and panel practice, and has been a valued member of the Council of the British Medical Association, chairman of the Scottish Committee, and member of other Association committees.

### EDINBURGH SICK CHILDREN'S HOSPITAL

At the annual meeting of the Royal Edinburgh Hospital for Sick Children Sir John R. Findlay, who presided, remarked that for the first time for many years the total expenditure during the year had exceeded the total income, both from subscriptions and from legacies, and in consequence the amount of invested funds was smaller than it had been a year ago. He considered that the amount contributed by the charitable public in Edinburgh constituted unfavourably with the support received from county districts. The ordinary income for the year had been £11,677, and the ordinary expenditure £17,188. He referred to the scheme for the institution of an orthopaedic centre in Edinburgh, and said that the directors of the Children's Hospital were watching developments with interest and with every desire to assist in the movement. The report by the directors of the hospital showed that the number of cases treated in the wards last year was 2,956, as compared with 2,968 in 1925. Of these, 1,593 were medical and 1,248 surgical. The average daily number of patients in hospital during 1926 had been 115, and the average duration of treatment seventeen days. The total attendances at the out-patient department had been 25,604. A large number of patients had been treated in the sunlight department, and this had involved the provision of further accommodation, but many patients had derived striking benefit from it.

### EDINBURGH VETERINARY COLLEGE

At the annual distribution of prizes of the Royal (Dick) Veterinary College, Edinburgh, Bailie Dr T. G. Nasmyth presided and the Lord Provost distributed the prizes. The chairman remarked that the veterinary surgeon had, to a certain extent, been displaced by the advent of the motor car, and the consequent diminution of veterinary work among heavy draught horses and carriage horses, but a new sphere had been opened up by the association of the veterinary practitioner with public health administration in safeguarding meat and milk supplies, and the appointment of county veterinary inspectors afforded a new and wide field of work. The college had gradually developed a post-graduate side to its work, with a view to preparing men for specialist appointments. The college, however, was fully alive to the fact that the specialist formed only the smaller part of the profession, and that the general practitioner must remain its backbone.

## South Africa.

[FROM OUR CORRESPONDENT IN CAPE TOWN]

### THE HEALTH OF CAPE TOWN

THE annual report of the medical officer of health of the city of Cape Town (Dr T. Shaduck Huggins) for the year ended June 30th, 1926, states that "Until the year 1924-25 births and deaths were recorded on two bases—namely (1) 'crude,' including all births and deaths which occurred in Cape Town, and (2) 'corrected for visitors,' obtained from the 'crude' figures by deducting births and

deaths of non-residents which occurred in Capetown (outward transfers). There was not available complete information about births and deaths of Capetown residents which took place outside Capetown (inward transfers), and it was therefore not possible to obtain figures fully corrected for inward as well as outward transfers. The director of census recently brought into operation a system whereby, in regard to Europeans, only he furnishes to medical officers of health lists of outward and inward transfers (births and deaths) and 1924-25 was the first year in which this information was available for the Capetown statistic. In making the corrections for those transfers, the figure of the director of census and statistics are accepted for inward transfers, but for outward transfers the figures obtained by the medical officer of health from the local registration returns are taken in preference to the lists supplied by the director of census and statistics."

The information from the director of census and statistics in regard to inward transfers applies only to European, and therefore does not enable the statistics as to non-Europeans or the total population to be corrected for inward transfers. It is considered to be desirable that the system should be applied to the non-European population also.

The census of population which was taken at midnight between May 4th and 5th, 1926, considered in conjunction with the census of May 3rd and 4th, 1921, has enabled more satisfactory estimates of the population of the municipality and of its constituent wards to be made for the year under review than was the case in the immediately preceding years. This is especially so in regard to the non-European population, the estimate of which was previously not on a satisfactory basis. In the country generally the intermediate census of 1926 was confined to Europeans, but arrangements were made to include non-Europeans also in Capetown and certain other municipalities. The decennial census of 1921 included both Europeans and non-Europeans.

The provisional results of the census of 1926 show the population of the municipality of Greater Capetown to be as follows: Europeans 112,548; non-Europeans, 99,652—total 211,600. The latter named figure includes 16 Europeans and 4,042 non-European representing the occupants of the native location at Vredenburg included in the municipal area in 1921. The municipal area amounts to 37,847 acres and the length of the main road passing from one boundary of the municipality to the other is about twenty-five miles.

The births registered during the year 1925-26 numbered 7,106 (2,524 European + 580 non-European and 2 of unknown race). The birth rate per 1,000 population is therefore as follows: European 22.65 (uncorrected) 20.93 (corrected for outward transfers) 22.01 (corrected for outward and inward transfers). Non-European 49.55 (uncorrected) 48.55 (corrected for outward transfers). All classes 34.82 (uncorrected) 33.47 (corrected for outward transfers). The difference between the number of births and deaths is the natural increase in population. This for all classes amounted to 3,323 (uncorrected) and 3,368 (corrected for outward transfers) for Europeans 1,242 (uncorrected) 1,256 (corrected for outward transfers) and 1,339 (corrected for outward and inward transfers) and for non-Europeans 2,083 (uncorrected) and 2,133 (corrected for outward transfers). It will be seen from these figures that in spite of their higher death rate the natural increase of the non-European section of the population exceeded that of the European section by 760.

The number of male births per 100 female births (excluding births in Capetown which did not belong thereto) was 98.96 amongst Europeans and 99.56 amongst non-Europeans. In 1924-25 the corresponding figures were 104.1 and 106.3. In 1923-24 114.2 and 106.5 and in 1922-23, 98.8 and 107.7. The percentage of illegitimate births to total births (corrected for outward transfers) was 4.67 amongst Europeans and 24.20 amongst non-Europeans. The number of stillbirths registered during the year was 458 of which 89 were European, 368 non-European and 1 of unknown race.

The deaths registered during the year 1925-26 as having taken place in Capetown numbered 3,777 (1,222 European 2,492 non-European and 3 of unknown race). The death rate per 1,000 of population is therefore as follows—European 11.50 (uncorrected) 9.66 (corrected for outward transfers) 10.00 (corrected for outward and inward transfers). Non-European 26.91 (uncorrected) 25.52 (corrected for outward transfers). All classes 18.51 (uncorrected), 16.87 (corrected for outward transfers). Both the European and non-European death rates for the year under review are the lowest recorded since notification in 1915.

It will be observed that 1925-26 was a favourable year in regard to mortality from measles and whooping-cough and also from apoplectic and respiratory diseases. The decline in deaths from enteric fever which had shown itself in recent years has continued the mortality from that disease in 1925-26 being the lowest on record. From diphtheria however the mortality continued somewhat high. The mortality from tuberculosis was less

than in the previous year but still especially amongst the non-European failed to show the diminution compared with the previous ten years that might be hoped for from diarrhoeal diseases the mortality rate being high amongst non-Europeans but amongst Europeans rather low compared with previous years. The deaths from heart disease, rheumatic fever and influenza were above the average and the recorded death rate from cancer continued to increase.

The deaths of children under the age of 1 year registered during the year 1925-26 numbered 657 (161 European 493 non-European and 3 of unknown race). The infant mortality rate per 1,000 births there was as follows—European 65.8 (corrected for outward transfers) 62.37 (corrected for outward and inward transfers). Non-European 175.9 (corrected for outward transfers). All classes 133.21 (corrected for outward transfers). The European rate for the year under review is the lowest on record but the non-European rate was lower in the years 1921-22 and 1924-25.

## Correspondence.

### BRITISH MEDICINE

SIR,—Sir Robert Philip's admirable address and the excellent paper by Professor Hey Groves in your issue of July 23rd suggest to me the desirability of putting forward two considerations impressed upon me by a recent survey of the history of medicine, namely:

1. There is no intellectual calling in this country which has rendered more conspicuous service to the Empire, in the last hundred years, than British medicine.

2. Is it not time that British medicine as much as any other responsible intellectual calling in this country, made herself mistress in her own house?—I am, etc.,

Exeter July 2 h.

W. GORDON.

### MINERS' NYSTAGMUS

SIR.—The contributions from Drs Fergus and Potson in your issue of June 18th (pp 1092, 1094) on miners' nystagmus are very interesting and open up a vast field for speculation. Yet two facts seem to stand out: (1) The class of miner generally affected is the actual collier. (2) The suggestion of retinal exhaustion as the actual cause—that is, fatigue on action and recovery after rest.

The fact of the incidence of the disease prior to the strike and the great lessening of the number of cases following the industrial upheaval is too potent an argument to be neglected. People who so strongly resented the action of these men during and since the strike might find in this some reason to pause and reconsider their position. It would be interesting to know whether observers had noted the condition of the pupil in these cases. They quote other evidence of disturbance of the sympathetic system.—I am, etc.,

O. W. T. BALDWIN, MRCS, L.P.C.P.

London S.W.8 June 28 h.

SIR,—I can assure Drs Haldane and Llewellyn that I have read the reports very carefully, but I do not find in them any statement about the candle-power deemed to be necessary for the prevention of nystagmus. I have not committed myself to any view as to the cause of nystagmus, but think there is no evidence that it is due to defective illumination and I have found as a matter of experience that the brighter the light the worse the nystagmus. Up till now, so far as the area in which I work is concerned, the electrifying of the pits has not been successful in eliminating nystagmus.

Professor Collie I think, has made a slight error, in so far as he did not take account of the fact that there was no nystagmus in the American pits prior to the introduction of the electric cap lights approved by Dr Haldane.

Dr Gordon Wilson's letter is an interesting one. The question, perhaps, that he would bring before his own mind is this: Why should occupational deafness occur in some mines and not in others? There are six safety lamp pits in the Tanarashire district in which there is no nystagmus.

been a case of nystagmus. The disease is rife in some pits, in others it occurs but only very occasionally—I am, etc.,

Chesham, July 18th

FREDLAND FERGUS

\* We referred this letter to Dr J S Hildane, who has made the following reply. With its publication we must bring this correspondence to an end.

Sir,—If Dr Fredland Fergus will look again at our paper under the subheading "Illumination," he will see that we estimated that in order to prevent miners' nystagmus the illuminating power of a hand safety lamp would need to be increased to about three candles, as compared with only about 0.7 given by the present electric lamps. An improved flame safety lamp without a mantle, giving three candles, was shown at the meeting where our paper was read, and another, with a mantle, giving nine candles. It is true that the surface of the filament of an electric lamp is far more brilliant than that of a flame lamp, but the extent of surface in the flame lamp is so immensely greater that a good flame lamp gives much more light than an ordinary electric lamp of the present type.

As regards American pits, it is only in recent years that the use of safety lamps has become widespread, and the safety lamp used is the electric cap lamp, which, for the reasons explained in our paper, gives a far better illumination than the hand electric lamps used in this country.

It does not seem to me that there is even a semblance of real evidence for the statement that "the brighter the light the worse the nystagmus"—I am, etc.,

Oxford, July 22nd

J S HILDANE

#### ADRENALIN EFFECTS AT THE MENOPAUSE

Sir,—Dr Wise, in the *BRITISH MEDICAL JOURNAL* for July 16th (p. 115), raises some interesting objections to my conclusions concerning the causation of "flushing" at the menopause, which were published as a preliminary communication in the *BRITISH MEDICAL JOURNAL* for July 2nd (p. 14).

He suggests that since the "flushings" pass off within a few years, at a time when the ovaries are secreting less than while the flushings were complained of, my theory that the flushings are caused by an unrestrained action of the suprarenals, the internal secretion of the ovaries being deficient or absent, is open to objection. Our knowledge of the endocrine system at the present time shows that there exists not only an organic harmony between the glands, but a compensatory interaction also. My experimental work has shown that the hyperactivity of suprarenals in women at the menopause is increased in intensity if the removal of the internal secretion of the ovaries is abrupt, for example, in those women in whom the ovaries have been removed by operation.

I maintain, therefore, that the disturbance of the suprarenals at the menopause is a temporary phenomenon which passes off when the endocrine system in general exercises its compensatory activity, and makes up for the sudden disturbance caused by the loss of the internal secretion of the ovaries—I am, etc.,

JOHN H. HANNA, M.D. Cantab

London W 1 July 16th

#### DIGITALIS IN INFLUENZA

Sir,—The address by Mr L B Turner in your issue of July 16th (p. 93) on influenza emboldens me to call attention to the immense value of digitalis in epidemics where signs of myocardial trouble usually appeared as was the case in 1889 and the following three or four years. Acute cardiac dilatation was common on assuming the erect position, usually on the third day. I have had three cases in a morning. I treated every case of influenza for several years with digitalis, and with other remedies, and attributed the entire absence of deaths—in very fatal epidemics—to this drug.

The rapid pulse observed in the last two epidemics has been noticed to coincide with enlargement or tenderness of the thyroid, and this has been more or less successfully treated by tincture of iodine, with or without tincture of digitalis. I found a tendency to relapse, however, and the iodine had to be administered for several weeks—I am, etc.,

Winchester, July 16th

F R HUMPHRIS

#### DRUGS FOR SLEEPLESSNESS

Sir,—The following case may be of interest in support of the view that tolerance to veronal does not become established.

I was called to see a man of 57, at 5.30 on a Tuesday morning as his wife was anxious about his very stertorous breathing, and she was unable to rouse him. She told me he was in the habit of taking veronal, and thought he was so used to it that he could take large doses. She was afraid he had taken some the night before but was not certain. I was unable to rouse him to consciousness, but could stimulate him to movements of his limbs. Reflexes were normal.

I treated him for veronal poisoning, washing out the stomach and colon, and giving strychnine, digitalis, and caffeine hypodermically every four hours. At midday he was much more conscious, and movements could no longer be stimulated. At 6 p.m. his breathing became impaired by oedema of the lungs. This yielded during the night to atropine injections, but pulse and respiration became very poor at times.

By the morning his condition had somewhat improved, but he showed no signs of consciousness. I was able to feed him three times during the day by the stomach tube with milk, coffee, and brandy. He was also having saline and glucose by rectum. He had no return of oedema of the lungs. During the night his condition remained much the same, the pulse fluctuating in character. The next morning (Thursday) he was obviously not so well, and in spite of stimulants, camphor, caffeine, and strychnine, his respiration and pulse failed, and he died at midday.

During the first day I was able to have analysed the remains of a powder in a tumbler, which proved to be veronal, and 5½ ounces of urine which I drew off was found to contain 6 grains of veronal. It was estimated that he had taken about 50 grains.

This patient was of a cheerful disposition and had no worries. He had been to the theatre the night before, but went to bed with a headache, and expressed the hope that he would have a good sleep, as he frequently did not sleep well. It appeared that he had obtained a little store of veronal in France, of which he had not taken all. He had told his friends how well it suited him, and that he could take more than most people as he was used to it.

There was no question of suicide, but apparently he had been determined to have a good night's sleep, and had put too much faith in his tolerance to veronal—I am, etc.,

Lastbourne, July 6th

A DEAR

#### AN AUSTRALIAN DIPLOMA IN TROPICAL MEDICINE

Sir,—I was much gratified at the mention on page 485 of the *JOURNAL* dated March 12th, 1927, that one of the medical officers (Dr R L Bellamy) of the Papuan Medical Service had been the first to obtain the Diploma of Tropical Medicine at the University of Sydney, Australia. However, I was sorry that the Territory of Papua was not referred to. Australia is responsible for the administration of two tropical territories: (a) the Territory of Papua, which, until 1907, was named British New Guinea, and (b) the Territory of New Guinea, which, until the war, was known as German New Guinea. The first territory, that of Papua, is governed simply as a territory of Australia, and is not under mandate. It was from this territory that Dr Bellamy came. The territory of New Guinea is held by Australia under mandate. There is a certain amount of friendly rivalry between the two territories, and some here regret that your article on page 485 rather implies that Dr Bellamy, the first Australian D.T.M. and H., came from the mandated Territory of New Guinea (that is, late German New Guinea)—I am, etc.,

W M STILES, M.D., B.C.,  
D.T.M. and H. Camb.

May 25th

Chief Medical Officer, Territory of Papua

## Obituary

DR VINCENT JOHN MAGPANE, who died on June 17th, at his residence in Darlaston, was born in 1858, and received his medical education in Dublin, where he obtained the diplomas of L.R.C.P.I., L.R.C.P.S.I., and L.M. in 1881. In the following year he commenced private practice in Darlaston, and in 1894 became a member of the local district council, of which he was chairman in 1897 and 1910. He was appointed medical officer of health for Darlaston in 1910 and held this position at the time of his death. He took an active interest in the local Volunteers, which he joined in 1884, five years later he received a commission as lieutenant, was promoted captain in 1893, and major in 1906. He commanded a company in South Africa in 1902 and held the Queen's South African medal with two clasps, the Volunteer Long Service medal, and the Volunteer Officers' Decoration. He was a member of the British Medical Association.

DR CHARLES GASKELL HIGGINSON, who died on June 26th, aged 68, received his medical education at Manchester and Newcastle, he took the degree of M.A. Lond. in 1881, obtained the diplomas M.R.C.S., L.R.C.P. in 1886, the L.M.S.S.A. Lond. in 1907, and graduated M.D. Durh. in 1912. About 1900 he became specially interested in the sanatorium treatment of pulmonary tuberculosis, and held a post for some time on the staff of Crooksbury Sanatorium. He published a life of Bodington and short practical contributions on sapraemic glycosuria and other medical subjects. He was a member of the British Medical Association. A colleague writes: Dr Higginson was a relative of the inventor of the Higginson's syringe, and also of James and Harriet Martineau. He was a man of brilliant literary gifts and was much in request at literary gatherings. He never forgot a friend or an old patient, and often went out of his way to do a service to an old comrade, he contributed freely to movements of public utility. Those intimate with him were impressed by his generosity, modesty, courage, sound common sense, and thoughtfulness for others.

THE LATE ARTHUR BOLLES LEE—Some extra copies of the portrait of the author of *The Microtome*, the *Index-Mecum* which was issued with the last number of the *Journal of Pathology and Bacteriology* are available, and may be had by anyone interested on application to the editor at 17, Loom Lane, Radlett, Herts.

## Universities and Colleges.

### UNIVERSITY OF OXFORD

At a congregation held on July 23rd the following medical degrees were conferred:

B.M.—W. N. Dickenson O. Hooper P. C. Probyn Williams J. W. Pugh  
H. W. Allen C. Charleson J. L. Glover P. F. Clover Irene M. Titcomb

### UNIVERSITY OF CAMBRIDGE

At a congregation held on July 14th the following medical degrees were conferred:

M.Chir.—R. S. Corbett  
M.B.—B. Chubb E. L. Alexander G. M. Tanner H. F. Griffiths  
H. P. Nelson E. S. Page  
B.Chir.—Y. C. J. Harris (by proxy) H. S. Allen C. F. Watt. H. M. Elliot  
C. E. Kellett D. N. R. Jones R. Watson

### UNIVERSITY OF LONDON

A MEETING of the Senate was held on July 20th the Vice-Chancellor (Sir William Beveridge) being in the chair.

#### London School of Hygiene and Tropical Medicine

The London School of Hygiene and Tropical Medicine (Department of Bacteriology and Immunology and of Epidemiology and Vital Statistics) was admitted as a school of the University. The date of the appointment of Professor W. W. C. Topley and Mr. Major Greenwood to the respective University Chairs of Bacteriology and Immunology and of Epidemiology and Vital Statistics teachable at the school was changed from August 1st 1923 to October 1st 1927.

#### External Students

The Senate have placed on a permanent basis the advisory Service for External Students, which has been working experimentally

for the past three years. Under this scheme external students may consult the External Examiners on any matters relating to their studies for external degrees.

#### Diploma in Biology

It was resolved to institute an Academic Diploma in Biology.

#### Appointment

Professor E. H. Kettle M.D. B.S. Lond. M.P.C.P. was appointed as from October 1st 1927 to the University Chair of Pathology, teachable at St. Bartholomew's Hospital Medical College. He is also at St. Mary's Hospital Medical School and obtained the M.B. B.S. Lond. in 1907 and the M.D. in Pathology in 1910. In 1910 he was appointed a pathologist and Lecturer in Pathology at St. Mary's Hospital and later Director of the Department of General and Special Pathology to the newly formed Institute of Pathology and Medical Research. Since 1924 he has been Professor of Pathology and Bacteriology in the Welsh National School of Medicine, Cardiff.

Dr. Bronislav Malinowski D.Sc. Lond. Ph.D. Cracow was appointed to the University Chair of Anthropology teachable at the London School of Economics.

Miss D. L. Mackinnon D.Sc. Aberd. was appointed to the University Chair of Zoology, teachable at King's College.

Mr. W. H. Lunnell Ph.D. M.Sc. Durh. was appointed to the University Readership in Pharmaceutical Chemistry teachable at the School of Pharmacy.

Sir Holburt Wynn M.S. F.P.C.S. was appointed representative at the nineteenth French Congress of Medicine to be held in Paris in October 1927.

#### Doctorate in Physiology

The following Doctorate was conferred—D.Sc. in Physiology. Mr. A. S. Lanks University College, for a thesis entitled: On the occurrence of the oestrous cycle after x-ray sterilization.

#### Results of Examinations

The following candidates have been approved at the examinations indicated:

M.D.—Branch I: Medicine. W. L. Ackerman Doris M. Baker J. Bevan Jones T. B. Blackledge F. T. Brain Grace D. Chambers J. C. M. Elmes G. J. A. James A. T. Jones G. Khoshk Marjorie Low H. V. Morlock Jean L. Smith Hilda N. Stoessiger H. C. C. Taylor J. Whitty Caroline I. Wright B.Sc. Ross Doris M. Stone Branch III: B.Sc. May K. Ruddy Branch IV: Women F. C. Alton H. Burr White (University medal) Dorothy N. L. Leverton Branch I: Sale Medicine L. A. Macdonald M.S.—Branch I: Surgery D. H. Patey

#### UNIVERSITY COLLEGE

The following awards have been made in the Faculty of Medical Sciences at University College—Entrance Scholarship I. P. Bettleby (first Memorial Prize) Margaret D. Wright Anatomy Gold medal (senior class) Flora Hargreaves Silver medal (junior class) D. Davidson Histology and Embryology Prize equivalent to silver medal Albertine L. Winner and D. Davidson (equal) Organic and Applied Chemistry Silver medal L. G. Norman Physiology Sharper Scholarship L. E. Bayliss gold medal (senior class) Flora Hargreaves Pharmacology Silver medal, Flora Hargreaves

#### LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN

The Council has awarded the following scholarships and bursaries for sessions 1927-28 to the value of £1400—St. Dunstan's Medical Exhibition Miss S. C. B. Waller Isabel Florence Scholarship Miss C. L. Taylor Miss F. D. Wainwright Mrs. George M. Smith Scholarship Miss J. G. Gould Mabel Sharman Crawford Scholarship Miss L. Reder Dr. Margaret Told Scholarship Miss D. H. Courtney Sarah Holborn Scholarship Miss C. S. Beer and Miss H. C. Tester Lady Butler Scholarship Miss M. C. Goodchild Alfred Lauzon Bursary Miss C. A. Coover Ellen Walker Bursary Miss V. H. Rieu Flora Murray Bursary Miss M. E. Roberts Dr. Edith Peckey Philip on Pos-Graduate Scholarship Miss G. H. Newell M.B. B.S. Lond. and Miss D. M. Scott M.B. Ch.B. Edin.

#### SOCIETY OF APOTHECARIES OF LONDON

##### Proposed New Diploma

THE EXAMINATIONS Committee of the Society of Apothecaries of London has drawn up a report which will shortly be presented to the Court of Assistants of the Society. The report recommends the institution at an early date of a diploma indicating specialized knowledge of the subjects of ante-natal care and infant welfare. It would be granted to registered medical practitioners who had been engaged in post-graduate study of the subjects both in practice and theory and a high standard of professional knowledge would be guaranteed by a stringent examination. The diploma would be specially adapted to the needs of the general practitioner who wishes to show that he possesses a knowledge and experience in the subjects of a higher grade than that demanded for legal qualification.

##### Results of Examinations

The following candidates have passed in the subjects indicated—SURGERY—L. Ashkenazy E. Clay Jones J. Miller J. D. D. E. A. S. round MEDICINE—Y. F. Engelen E. Clay on Jones W. H. Coles P. E. 10th F.P.C.S. MEDICINE—S. A. Carr L. C. L. or one S. Colman S. B. Smith MIDWIFE—L. Clayton-Jones P. F. Fennell J. D. P. The diploma of the Society of L. L. has been awarded to E. A. Stroud and L. Clayton-Jones.

## Medical Notes in Parliament.

(FROM OUR PARLIAMENTARY CORRESPONDENT.)

THE House of Commons this week completed its financial business for the Session, passing Estimates for many departments, of which only those for the Board of Trade, Board of Education, and Ministry of Labour were debated. The Trade Disputes and Trade Unions Bill and other measures passed through their final stages in both Houses and received the Royal Assent, after which Parliament adjourned till November 8th.

### Medical Confidences

On July 25th Dr Vernon Davies asked whether the attention of the Minister of Health had been drawn to the decision of one of His Majesty's judges at the Birmingham Assizes on July 18th, 1927, that there was no privilege for medical men to refuse information to the court obtained confidentially in the treatment of a patient suffering from a particular complaint, in spite of definite assurances in the past by the Ministry of Health that such information would be inviolate and, as this decision by the learned judge must exercise a deleterious effect upon the detection and treatment of this complaint by preventing sufferers from it seeking competent medical advice and treatment, what steps he proposed to take to implement the assurance given to such sufferers in the past that the information obtained by submitting themselves to treatment would be kept inviolate, and whether in view of the importance of removing any obstacle to complete confidence between a patient and his medical adviser in the early stages of this disease, he would inquire into the desirability of introducing legislation to give a doctor the right at least in the case of this disease, to refuse to give evidence about confidential information obtained from a patient. Sir K. Wood said the Minister's attention had been drawn to this case, and he proposed to give careful consideration to the points raised by it.

Dr Davies asked if the Minister would bear in mind when considering this question, that it is a matter affecting pinned patients, and that it might have deleterious effects on the treatment of disease and lead to a feeling of insecurity both by medical men and patients. Sir K. Wood replied that these were difficult questions to which the Minister of Health proposed to give careful consideration.

### Bills

In the House of Lords on July 25th a Commons amendment to the Diseases of Animals Bill was accepted. On the same day the Midwives and Maternity Homes (Scotland) Bill and the Medical and Dentists Acts Amendment Bill passed through Committee, and on the following day were read the third time and passed. The latter bill is to be considered by the Commons during the autumn.

### Nursing Homes (Registration) Bill

On July 26th a Standing Committee of the House of Commons considered the Nursing Homes (Registration) Bill. Amendments were made in a subsection which provides that registration may be refused to a maternity home which was not in existence at the commencement of the Act and where any person attending any woman in the home in childbirth or nursing such woman after childbirth is not a certified midwife, pupil midwife, or qualified nurse. On the motion of Dr V. Davies an amendment was made limiting the application of the words "woman after childbirth" to patients in the home. On the motion of Sir Richard Luce the Committee added a duly qualified medical practitioner to "certified midwife" and the rest of the list. Viscountess Astor moved that a nursing home (other than a maternity home) in which treatment by medical methods was not administered should not be refused registration on account only of the fact that it was not under the supervision of a qualified medical nurse or that there was not a proper proportion of qualified nurses. She proposed this in order to exempt Christian Science Homes which objected to being under medical men or medical nurses. Mr Chamberlain resisted the amendment. He pointed out that it made no reference to Christian Science, would permit all forms of untrained and irregular practice to claim exemption from the bill and would drive a coach and four through it. Dr Davies said that Christian Scientists recognized that medical men were necessary for broken legs or infections at all. Christian Science homes were common in all propositions charging the fees of the best nursing homes of the district and whose Christian Science practitioners charged the fees of medical practitioners. If they had competed with nursing homes they must be amenable to the law. Lady Astor renewed her appeal to the Minister to accept the amendment but Mrs Lawrence said that no people were more proved upon than the sick poor and the amendment would let through every quack in the world. Mrs Philip said that the amendment was far too wide. It was negatived without a division.

Mr Gerald Hirst moved an amendment to impose a time limit on the less stringent conditions which the bill provided for nursing homes in existence at the time of the bill's coming into operation. The limit proposed was that when the individual or corporation

not carrying on the home ceased to do so, the stricter conditions of the bill should apply to the new management, including the statutory obligation to maintain a proportion of qualified nurses. Sir Kingsley Wood advised the Committee to insert the amendment. He suggested that the amendment should be altered so that it would apply when the home ceased to be solely under the control of the original individual. Thus altered the amendment was accepted. Clauses 1 and 2 were added to the bill. Clause 3, dealing with notice of refusal or cancellation of registration was accepted with slight amendments moved by Dr Davies. On Clause 4 which provides that the local authority may make by laws among other matters, for a record being kept of children born in the home, Dr Davies moved to add also "any miscarriages occurring in the home." There was, he said, in undue proportion of miscarriage in certain nursing homes. The amendment was accepted. Sir Richard Luce moved to omit the proviso that along with the notification of death in a nursing home there should be given a statement of its cause. It said this would infringe the conditions of the Births and Deaths Registration Act 1926. Mrs Lawrence said that the bill was concerned with the deaths of women and children in maternity homes, and that there were certain types of homes which could not be watched too closely. Sir Kingsley Wood said he had consulted the Registrar General who in any case of suspicion would cause the information to be sent direct to the local supervising authority. This would keep the bill within the spirit of the Registration Act and action would be taken through an official of the State instead of on the initiative of a private informant. Dr Lemanth did not feel satisfied with Sir Kingsley Wood's explanation. He thought that a second line of inquiry was advisable. Sir Kingsley said he contemplated an arrangement whereby the Registrar General would inform the local supervising authority of the number of deaths in a particular home, and if that number seemed abnormal the officer of the authority would make inquiries. Sir Richard Luce wished to secure that unauthorized persons did not give the cause of death. Under the bill the midwife might have to give the cause of death. Dr Davies suggested that if the local authority applied to the Registrar General it should be permitted to inspect any certificate from any nursing home. Sir Kingsley Wood said he would see the Registrar General again and explain that the Committee desired the local supervising authority to be able to learn the cause of death. Whatever action was taken would be by instruction and not in the Act of Parliament. He suggested that Sir Richard Luce's amendment should in the meantime be carried. The amendment was carried and the clause added to the bill.

On Clause 5 (inspection of nursing homes) Sir Richard Luce moved an amendment to indicate that the medical officer of health was normally the proper person to inspect nursing homes. His amendment would make the clause begin "The medical officer of health of the local supervising authority or some other officer duly authorized by them may at all reasonable times enter and inspect." Sir Kingsley Wood approved the amendment. Mr Hirst thought that the bill should be further amended so that other inspectors, such as sanitary or architectural inspectors should act on the instruction of the medical officer. Mr Hirst's amendment was carried. Clauses 5 and 6 were then added to the bill. Debate arose on Clause 8, which defines the local supervising authority. Sir Douglas Newton moved an amendment to ensure that the larger non-county boroughs should be supervising authorities for nursing homes, non-county boroughs were already the principal public health authorities in their areas and had highly skilled medical officers. Dr Lemanth suggested that the Committee should also discuss a subsequent amendment in his name, which provided that a borough or urban district council might delegate its powers to the county council. Under the Midwives Act every midwife was registered and supervised by a county council or county borough council and these were the inspecting authorities under the Maternity Homes Act. Why should the Committee now multiply the inspecting authorities? The Select Committee on Nursing Homes had pointed out that interest or prejudice might affect inspection by the minor local authorities. The County Councils Association thought that to accept Sir Douglas Newton's amendment would be a retrograde step. If it was necessary to have a compromise on Sir Douglas Newton's amendment he suggested that the Committee should provide that where the council of any borough or urban district of which the medical officer of health is precluded from engaging in private practice shall resolve that the powers of a local supervising authority under this Act would be more efficiently administered by them without detriment to the administration of the Midwives Act, the county council may by resolution delegate such powers to that council and that council shall thereby become the local supervising authority under this Act.

Sir Kingsley Wood said he had endeavored to get the parties to come to an arrangement. He thought the most reasonable compromise was to allow the local authorities to become supervising authorities only when they had full-time medical officers of health. It would be undesirable for a small local authority to be the supervising authority when its medical officer was in private practice. Sir Richard Luce objected to supervision being committed to rural districts which only shared in a medical officer of health. Sir Kingsley Wood said the question would be reconsidered later. The Committee then divided on a consequential amendment proposed by Sir Douglas Newton which was carried by 14 to 6. This provides that the inspecting authority shall be (a) as respects a county borough the council of the borough (b) as respects an urban or rural district the medical officer of health of which is precluded either by the terms of his appointment as such medical officer or by the terms of any appointment when he may hold as medical officer of an other local or public authority from engaging in private practice the council of the district (c) as respects any other rural district the council of the county. Dr Lemanth's amendment was not put.

Clause 8 and subsequent clauses were added to the bill. On Clause 9 Sir Richard Luce moved that in any premises used or intended to be used for the reception of and the provision for a class of patients in whom the requisite nursing can be suitably and adequately provided by nurses of a class whose names are contained in some part of the register of nurses required to be kept under the Nurses Registration Act 1919, other than the general part of that register, references in the definition of "qualified nurse" contained in Subsection (1) of this section to the general part of the register shall be construed as including references to that other part of the register. Sir Kingsley Wood said this referred to children's nurses in homes exclusively for children and to male nurses in infirmaries. The clause was accepted. Mr. Hurrell moved a new clause to provide that in the County of London the supervising authorities should be the London County Council and the City of London Council with power to delegate to borough authorities and with uniform by-laws throughout the area. This amendment was carried and the bill reported to the House. The concluding stages of the bill will be taken during the autumn sittings of Parliament.

#### Nique

A number of questions were addressed to the Minister of Health about a grain ship which arrived recently in the Port of London and had been certified by the port sanitary authority to be suspected of containing vermin (rats) infected with bubonic plague. So far as he was aware no other vessel so suspected had arrived. All vessels from South American ports bound for the Port of London were boarded at Graysend. The port sanitary authority was taking all necessary precautions to prevent the spread of infection.

**Medical Benefit**—The Minister of Health stated on July 26 that the proposal of the Royal Insurance that the scope of the Act should be extended to include a consultant and a second medical officer when it decided to give the communicating its final views.

**Persons Drunk while in Charge of a Vehicle**—The Home Secretary on July 26th said in reply to a question that the general practice was that a person arrested for being drunk while in charge of a vehicle who demanded to be examined by his own doctor was not allowed to be examined in private the police insisting on being present. He did not see how the interests of the prisoner could be prejudiced by the presence of a police officer who might have to give evidence in court with regard to the examination. Interviews with solicitors were obviously on quite a different footing.

**Mule spinners' Cancer**—On July 25th Sir Frank Sarder asked the Home Secretary if his attention had been called to the report of the departmental committee on the occurrence of epitheliomatous ulceration among mule-spinners (mule-spinners' cancer) which attributed the absence of evidence of a similar incidence among cotton mule-spinners in France, Germany, Russia, Poland and America to the comparatively small number of mule-spinners employed abroad and in view of the fact that the more probable explanation for the absence of the disease in mule-spinners in foreign countries mentioned was the fact that in those countries braces were not worn but a belt only. He would consider the desirability of making a regulation that all spinners should wear belts instead of braces and of directing a further exhaustive inquiry into the fact as to whether or not there was at the present time a spray of oil which could reach the spinner's neck. Sir W. J. Wood said that alterations in the machinery containing the mule-spinners' cancer. Sir W. J. Wood said that the suggestion in the question as to the cause of this disease was not so far as he was aware supported by any evidence. The experiments of the Committee had proved that the oil thrown off from the bobbins could reach the spinner and no further inquiry on this point was necessary. No question arose however at present of requiring any expensive alterations to the existing mules. The Committee recommended that the employers and operatives a committee should endeavour by experiments to devise some form of simple and inexpensive guard which could be easily added to any existing mule and he was looking to the industry to give effect to this recommendation.

**Birth Rates**—Sir K. Wood on July 19th told Sir V. Durrant that the birth rate per 1,000 of the population in Great Britain in 1925 was 18.6 and in 1926 18.1. In France in 1925 it was provisionally 18.8, in Finland in 1925 it was 22.5 and in Germany 21.3. In the Netherlands in 1926 it was provisionally 23.8, in Spain in 1925 it was provisionally 29.4 and in Hungary in 1926 it was provisionally 26.7. In Italy in 1925 it was provisionally 27.5. In the only parts of Russia in Europe for which figures were available there were Soviet Republic of Russia 1924 43.6 (provisional) Ukraine 1923 35.4.

#### Notes in Brief

Mr. Churchill does not propose to introduce legislation to increase the Civil List pension to provide State recognition of self-sacrificing and devoted services to medicine and science.

Dr. Shields M.F. has been appointed a member of the Commission which is to go to Leyton to report on the revision of the constitution of that colony.

Commodore King in reply to Mr. T. Kennedy on July 26th said there had been twelve deaths this year in China among the British troops and two among the Indian troops not forming part of the permanent establishment there. Eight of the cases were due to illness and the rest to accidents or wounds.

Dr. Orr by Gore stated on July 25th that the local hygiene in the Straits Settlements was receiving the constant and careful attention of the local Government. The reconstitution of a Colonial Office advisory committee on methods of dealing with prostitution in Hong Kong, the Federated Malay States, Malta and Cyprus was under consideration.

In the year ended June 30th the police instituted proceedings in 180 cases for the emission of miasmatic or noxious vapours by vehicles in Blackwall and Potherhithe tunnel. Owing to legal difficulties no proceedings were taken for similar offences in the street of London.

## Medical News.

**DR A. NAVE KINGSBURY, M.B. B.S. B.Sc. Lond.** Colonial Medical Services, Institute of Medical Research, Federated Malay States has been awarded the North Borneo Forces Memorial Medal for the year 1926 for his paper "Some investigations of malarial fever," published in the *Transactions of the Royal Society of Tropical Medicine and Hygiene* (vol. xix No. 8). This medal is awarded annually for the best paper on tropical medicine or hygiene published in any journal during the preceding twelve months by any medical officer of under twelve years' service of the Royal Navy, Royal Army Medical Corps, Royal Air Force, Indian Medical Service or of the Colonial Medical Services.

**THE thirty-sixth French Congress of Surgery** will be held in Paris under the presidency of M. Paul Béhari, professor of choical surgery at Bordeaux, from October 3rd to the 8th when the following subjects will be discussed: (1) Drainage in abdominal surgery introduced by M. Cadeval of Paris and Pate of Lyons; (2) Chronic pericystitis and epiploitis introduced by M. Lardinois of Paris and Silhol of Marseilles; (3) Indications and results of peritoneal sympathectomy in surgery of the limbs introduced by M. Leriche of Strasbourg and Robineau of Paris.

**THE Fellowship of Medicine** announces that a special afternoon course in diseases of infants will be held at the Infants Hospital from August 8th to 21st with special visits to the Model Pasternizing Plant, Willesden, the Home for Blind Babies, Chorley Wood and the V.D. Central Babies Inn from August 23rd to September 10th. An all day course at the Queen Mary's Hospital, Stratford will include demonstrations of surgical, medical orthopaedic and ophthalmic cases operations and lectures. In September there will be courses in medicine, surgery and the specialties at the Westminster Hospital, diseases of children at the Queen's Hospital, psychological medicine at the Bethlem Royal Hospital, ophthalmology at the Royal Westminster Ophthalmic Hospital and orthopaedics at the Royal National Orthopaedic Hospital. The Fellowship also arranges a general course of instruction at the associated hospitals. Copies of all syllabuses may be obtained from the Secretary of the Fellowship, 1 Wimpole Street W.1.

**THE annual dinner of past and present students of St. Mary's Hospital Medical School** will be held at the Cunningham Rooms, Great Queen Street on Saturday, October 1st, at 7 p.m.

**THE house of the Royal Society of Medicine** will be closed during August for cleaning and repairs. The library will be open on weekdays (excluding Monday August 1st) from 11 a.m. to 6 p.m. except on Saturdays when it will close at 1 p.m.

**THE late Professor E. H. Starling** we learn from the *Artist's Pictorial Journal* joined that corps in 1909 when he was holding the Jodrell Chair of Physiology at University College. He took with him a number of his students.

**DR PERHANS** professor of obstetrics at Vienna has been elected rector of the university.

**THE Medical Society of the Mediterranean Coast** has arranged a tour from December 30th 1927 to January 7th 1928 open to all medical practitioners and their families starting from Toulon and visiting Hyeres, St. Raphael, Valence, Cannes, Le Cannet, Grasse, Vence, Nice, Villefranche, Beaulieu, Monaco, Monte Carlo and Mentone. The cost as at present arranged will be 1500 francs including hotels and motor car excursions apart from the cost of the railway journey for which it is hoped facilities will be granted by the railways. Further information may be obtained from the French National Touring Office 55, Haymarket London S.W.1.

**A CONGRESS of Alimentary and Metabolic Diseases** will be held at Vienna from October 4th to 7th when papers will be read on the regulation of metabolism, peculiar formation of calcium and diabetes by Drs. Hober, Porges, V. Koranyi, Tandler, Herxheimer, Schurz, Faltz and others. Further information can be obtained from the general secretary, Professor von der Velden, Bambergstrasse 47, Berlin, W. 30.

The twelfth International Congress of Hydrology, Climatology, and Geology will be held at Lyons from October 8th to 11th, with Professor Gilbert of Paris as president of honour and Professor Pic of Lyons as president. The subjects to be discussed include acid base equilibrium and treatment by mineral waters, atmospheric radio activity, and the geological origin of radioactive mineral waters. The secretary is Professor Pic of Lyons.

The nineteenth French Congress of Medicine will open in Paris on October 11th, under the presidency of Professor Pierre Leissier, and will continue to the 15th, it will be followed immediately by the celebration of the centenary of Villermé. The programme includes discussions of the symptomatology of the medical septicaemias, the pathology of the occlusas, and the medical indications and therapeutic value of splenectomy. It is proposed to arrange an excursion to the battlefield of the Aisne. Detailed information may be obtained from the general secretary, Dr M. Chiray, 14, Rue Pétiarque, Paris, XVIe.

A POST GRADUATE course in the pathology of the digestive system will be held in Barcelona from October 5th until Christmas. Further information may be obtained from Professor Gallart, at the Hospital de la Santa Cruz, Barcelona.

There are at present 5,000 medical students in Paris and 8,800 in the whole of France.

NINETY EIGHT cases of encephalitis lethargica, with 37 deaths occurred in Germany in 1926, as compared with 217 cases in 1925. Notification is compulsory only in Baden, Brunswick, Lüneburg, Prussia (since May, 1926), Anhalt (since July, 1926), and Schaumburg Lippe (since June, 1926).

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1 on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the JOURNAL, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9861, 9862, 9863, and 9864** (internal exchange, four lines).

The TELEGRAPHIC ADDRESSES are **EDITOR of the British Medical Journal, Antology Westcent, London**.

**FINANCIAL SECRETARY AND BUSINESS MANAGER** (Advertisements, etc.), **Antology Westcent London**.

**MEDICAL SECRETARY** **Mediscia Westcent London**.

The address of the Irish Office of the British Medical Association is 16 South Circular Street, Dublin (telegrams **Bacillus Dublin**), telephone 4737 Dublin, and of the Scottish Office, 6 Drumshengill Gardens Edinburgh (telegrams **Associate, Edinburgh**), telephone 4361 Central.

## QUERIES AND ANSWERS

### TREATMENT OF ONYCHIA

"W.S.M." asks for advice in the treatment of a typist, aged 39, who has onychia of the index finger of both hands, the right being the worst. She is otherwise healthy, but the forefinger being the pettenion finger, the lesion is serious for her.

### GRAFTING FOR CORNEAL SCARS

Dr C. F. SHILL (Hendon) writes with reference to an inquiry published on July 16th (p. 121). There seems to be no justification for attempting so hazardous an operation as grafting for dealing with corneal opacities. The more so since it was shown a few years ago that corneal scars, whatever their size and density, are speedily and painlessly resolved by a few short applications of a mild "violet ray" current, the glass applicator being in contact with the closed lids.

### LEASING TAX

#### Motor Car Pent Average

"I.H.T." replaced his car in January, 1925. On what figure should his depreciation allowance be based? He has bought his premises, should he not be allowed to deduct a proportion of his former rent? Can he not claim the three years average seeing that he took over the practice at April, 1924, and that his earnings have been increasing?

\*. (1) The depreciation allowance is based on the written down value of the car at the end of the last account prior to the year of assessment. That principle has been approved by the courts. If the obsolescence allowance is claimed in respect of the car replaced there should be no effective difference in this case. (2) As from the date of purchase of the premises the rental value to be taken as the basis of the deduction for Schedule D is the amount on which tax has been paid under Schedule A, it should be borne in mind that an appropriate portion of the expenditure on repairs and decorations should also be claimed. (3) In the circumstances stated "I.H.T." can elect to take the three years' average for 1927-28 and 1928-29 (both years, not one only), if the earnings for the year 1923-24 were greater than either of the years 1924-25 or 1925-26, but not otherwise. The election should be notified to the inspector of taxes by October 5th, as made under Section 29 of the Finance Act, 1926-27.

### Motor Car Taxation

"D.I.A." sold his former practice in March, 1925 and bought another three months later. He has claimed obsolescence in respect of a car sold in 1926, and the local inspector claims to deduct the sum of £102 as being the wear and tear attributable to the period before "D.I.A." took over his present practice.

\*. We advise "D.I.A." to accept the inspector's objection as regards the £11 attributable to the three months during which he was not in practice, but as regards the remaining £91 the contention is clearly inequitable. In substance the inspector is treating the claim as if the car had been sold by the old practice to the new one, but we presume that he would not regard the facts as justifying the present proprietor of the old practice in claiming a deduction of £91. If so it is clear that unless that allowance is made to "D.I.A." the plain intention of the Statute is defeated. There is some technical ground in the suggestion that the old loss by a car and taxi did not affect the earnings of the practice for which "D.I.A." is now assessed, but, on the other hand, no allowance has been "made" for that wear and tear, and our correspondent did item the whole of the expense in 1926. If the inspector continues to refuse the claim perhaps a ruling could be obtained from the Secretary, Inland Revenue, Somerset House, in that event we should be glad to learn the result, as it is a matter of some general interest to the profession.

### Motor Car Transaction

"M.I." sold a car (which he had purchased second hand for £35) for £30 and bought a new car for £275. The inspector will allow £275-£30=£245 but not £335-£30=£305. The second car has since been replaced.

\*. We advise "M.I." to accept the £245 deduction. Where a second hand car is replaced by a new one the question of improvement and consequent adjustment for capital outlay raises peculiar difficulties.

## LETTERS, NOTES, ETC.

### THE EFFECT OF BATHING ON THE EARS

Mr F. FRANK STURM M.Ch. (Leigh, Lancs.) writes: In reply to overword of Mr C. Hamblen Thomas timely communication on "The effect of bathing on the ears" (**BRITISH MEDICAL JOURNAL**, July 9th, p. 78) with the single exception of the word "meati" used as the plural of "meatus" which it is not "meati" is as obvious to the mental ear as contaminated sea water to the physical organ.

### INTRATUMORIAL AMPUTATIONS

Dr JON TROTTER (Grimsby) writes: I was called at 4.30 a.m. to a woman who was expecting her second child. She was in labour. The presentation was a breech, left sacroanterior. The os was dilated to two fingers. It was called again at 9.30 a.m. and found the cervix fully dilated, the breech well down on the perineum, and the membranes unruptured. After rupturing the membranes which were very tough, a stillborn male child weighing 5 lb. was easily delivered. Both legs were abraded below the knee and the right arm ended at the elbow. The stump of the left leg presented an appearance like that of an old amputation through the knee joint, the patella being removed. The right presented a similar appearance but the medial condyle of the femur was absent. The child otherwise appeared normal. The mother aged 35 years gave birth six years ago to her first child, a girl, who presents no structural abnormality. There have been no miscarriages. The parents are healthy well married, and do not know of any birth deformities in their family histories.

### VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals will be found at pages 31, 32, 33, 36 and 37 of our advertisement columns and advertisements as to particulars, assistantships, and locum tenencies at pages 34 and 35.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 89.

## A Discussion

ON

THE REPORT OF THE LUNACY COMMISSION  
(ENGLAND)THE PROVISIONAL TREATMENT ORDER OF  
THE ROYAL COMMISSION

BY

GEORGE M. ROBERTSON, M.D.

President of the Royal College of Physicians of Edinburgh,  
and Professor of Psychiatry in the University  
President of the Section

The lunacy laws of England and of Scotland are in urgent need of amendment. The parent Act for Scotland dates back to 1857, since when great changes affecting its serviceableness have taken place in the social life of the country as well as in the scientific world. It however, definitely recognizes the paramount position of the medical profession in the treatment of mental diseases, for under its provisions no layman or magistrate is called upon to interview the patient before he is placed in a mental hospital and no layman or committee is held to be responsible for his removal when recovered. Medical men discharge these and all similar duties and to this feature must be ascribed the success of the Scottish system. It has gained the confidence of the people and in place of misgivings and suspicion, there is pride in our mental hospitals and in their management. No case of improper detention has ever been recorded in the law courts. The 1857 Act has served its day and generation well, and its principle of medical responsibility is in Scotland established for ever.

The principal Act for England was passed in 1890 and from the legal and administrative points of view it is a complete, logical, and accurately drafted instrument. Its very perfection in these respects has been a calamity to the person sick in mind. That the treatment of insanity is primarily a medical question, that insanity being a disease like other diseases must be treated and treated early if its cure is to be effected, were minor considerations in the framing of this Act. They were overshadowed by problems connected with the liberty of the subject and with the haunting fear of improper detention, which loomed so ominously in the minds of law makers. Thus, as has happened so often, an Act designed for the welfare of the insane person has turned out in practice to be to his detriment and has enacted with the object of reducing the sum of human misery have, in fact, increased it.

*The Recommendations of the Royal Commission*

The present is an opportune time to discuss the problems of lunacy legislation. A thorough and impartial inquiry by a Royal Commission has just been concluded and an exceptionally able report has been presented, pointing out existing defects and making valuable suggestions for the future. One gratifying and immediate result of the investigations made has been to allay all anxiety in the minds of reasonable people as to the improper detention of sane persons in mental hospitals in England. Such cases have not been found and in future legislation should not be dominated, as it has been in the past by suspicion and misgiving, which have done so much harm to the person chiefly interested—namely, the patient.

The following are some findings of the Commission:

- 1 The Commission did not find a single case in which improper detention had been suffered.
- 2 Five years previously a Select Committee of the House of Commons had also reported the same absence of improper detention.
- 3 The stigma of certification is acutely felt both by patient and his relative.
- 4 Certification should be the last resort and not a preliminary to treatment.

- 5 The present system of treatment is based on a very limited scale and needs radical reform.
- 6 The problem of insanity is primarily a medical problem to be dealt with on modern principles.
- 7 The keynote of the proposed new system is that the future should be prevention and treatment.

The problem before us is summed up by the Commission in the following paragraph:

The lunacy code should be replaced with a view to securing the treatment of mental disorder on a basis of medical responsibility to the treatment of physical ailments, a basis consistent with the special safeguard which are indispensable when the liberty of the subject is intruded.

According to the Commission the basic classification of cases requiring mental treatment should be—voluntary and the involuntary.

The arrangements suggested for voluntary treatment are on the whole satisfactory. The form of treatment will ultimately become by far the most popular and already in the Scottish royal hospitals the admission of voluntary patients paying the higher rates of board amounts to two-thirds of the total number. As the principle of voluntary treatment meets with universal approbation and differences of opinion exist only on matters of detail details on this subject would serve no useful end at present and therefore excluded.

With regard to involuntary patients three procedures are recommended by the Commission:

The simplest of the three is the Emergency Order signed by relative or friend or public official or one medical recommendation, which, as it is noted in not a certificate of insanity. This order remains in force for seven days. Nothing need be said regarding the emergency order which is altogether satisfactory.

We now come to the two remaining procedures recommended by the Commission: the Provisional Treatment Order and the Reception Order. The two orders are obtained through the personal intervention of a layman. They differ in three respects:

To obtain the provision 1 treatment order on day or only is called in to advise, instead of two as in the reception order, secondly the single doctor makes a recommendation in the provisional treatment order while the two doctors give certificates of insanity in the reception order and thirdly the authority of the provisional treatment order lasts from one to six months, while that of the reception order is indefinite in duration.

The Commission is to be congratulated on adopting the principle in the provisional treatment order that an insane patient whose recovery is expected may be detained and treated on the recommendation of a doctor without being certified to be insane, thus relieving the patient and his relatives of the stigma of certification which is felt by them so acutely.

The provisional treatment order is supported by the recommendation of one doctor only, this is a matter of no in so important a matter which is the most difficult, delicate and indefinite in the whole range of medical practice, according to Mr. Justice Macdonald, who said it should without doubt be considered. In every great profession there may be a first or second opinion, but the doctor, like other human beings, is liable to mistakes and may make mistakes or be deceived but the provision of two doctors falling into similar categories or of three in collaboration is a very rare contingency. As a safeguard against error or observer merely to remove the value of a first opinion, the employment of a second doctor is not in the opinion of the Commission a high standard, but with the approval of two doctors by the Commission the failure to recommend two doctors by the Commission.

Do you think a second certificate of insanity is of importance as a safeguard against error or deception? Two medical certificates have been employed in all pauper cases in Scotland for many years and for event years and should be employed in all cases in such case a well. Moreover the provision of a second certificate to private cases is vital as to proper medical economy where the liberty of the subject is concerned is indefensible but it is particularly objectionable to the medical profession when the failure to employ a second

\* A paper read in opening a discussion in the Section of Mental Diseases at the Annual Meeting of the British Medical Association in Edinburgh (Friday, July 22nd). Dr. H. C. Munn, a Commissioner of the Board of Control in Scotland, was in the chair.

doctor is, as we believe, partly responsible for the repeated visitations of a sick person by laymen, and these will certainly not make for economy.

Another very debatable point is the basis upon which the two classes of patient—namely those to be placed under the provisional order, and those to be placed under the reception order respectively—are to be selected. This involves the question of prognosis, notoriously the most difficult and uncertain problem in psychiatry. It has to be solved in the first place by the general practitioner, who can scarcely be expected to have the necessary experience, and secondly, by the justice, who has had no medical training at all. The provisional treatment order applies to those cases only in which "there is a prognosis of early recovery", and the reception order applies to those patients only who are not likely to recover within six months. Those who have already been under provisional treatment for six months naturally come under the second category.

The difficulty regarding prognosis may be illustrated by a recent experience. A very eminent surgeon treating a melancholic patient regarded the prognosis of the mental condition as hopeless, because the patient was intensely suicidal. A suicidal tendency is the most anxious symptom a patient can exhibit, but as regards prognosis it is of no more significance than an ingrowing toe-nail. The surgeon was astonished when he was told this truth, but he now knows better, for he saw the patient make a rapid recovery.

A justice under similar circumstances might very naturally make the same blunder and refuse to sign the provisional treatment order. It is obvious that prognostication and forecasting the date of recovery is not one of the easiest tasks in psychiatry, and should not have been selected in sorting out provisional treatment cases from reception order cases, even though it is desired, and very properly desired, that all patients who make early recoveries should receive the benefit of the provisional treatment order.

The happiest laws regulating practical affairs are not the fine product of a learning that flourishes in studies and in libraries, they are slowly fashioned by the friction of circumstance and the shock of facts in the rude school of experience. Were the recommendations of the Commission regarding involuntary patients passed into law every doctor would place every patient not hopelessly and memorably insane under the provisional treatment order. What experienced doctor will give a grave prognosis at the beginning of an obscure illness? If thirty-five years ago Sir Thomas Clouston objected to the name of "dementia praecox," simply because of the malign influence of a pessimistic nomenclature on the endeavours of the physician, what are we to think of the evil consequences of a serious prognosis given solemnly on oath as a preliminary to treatment? When remedies are forthcoming for incurable and fatal diseases like general paralysis of the insane what doctor, in the early stage of any illness, in cold blood, is, in vulgar language, going "to throw up the sponge"? Every successful doctor is an optimist, to be anything else is fatal to the prospects of his patients and to his own success. Gloomy deans may have a vogue, but not gloomy doctors. A gloomy outlook injures the patient directly, and it also does so indirectly by depressing the relatives and by creating an atmosphere of anxiety. It may be safely assumed, if the recommendations of the Commission be passed into law, that every patient not a chronic or absolutely hopeless case will receive the benefit of the doubt and will be treated under the provisional treatment order. In other words, all recent and recoverable cases of mental disorder will be given the chance of recovering within six months without being certified and registered as lunatics—"an excellent thing." No harm is done if incurable cases by mistake also enjoy this privilege, for it is clearly better to err on the side of granting it to too many than to too few. The intolerable self-reproaches and the awkwardness of the situation of a family doctor who, under the reception order, certified as insane a patient who made a perfect recovery in the course of three or four months, may be left to the imagination.

There is no doubt the Commission had the Scottish Schedule G in mind when it designed the provisional treatment order, for the powers granted for six months under this schedule can be applied to the treatment of a patient when "the malady is not confirmed" and "with a view to his recovery." This condition is better expressed in Schedule G than in the recommendation of the Commission, for the intention can always be honestly remedied, however faintly hopeful the outlook, and there need be no strain placed on the conscience by a declaration on oath that recovery is likely to take place within six months when the outlook is quite uncertain and when a definite diagnosis has not been made. Seeing that similar results can be obtained in a simpler, surer, and more honest way than by speculative prognosis and hazardous assessment of the date of recovery, it would be better to drop the dubious procedure of prognostication altogether and give every patient, not a chronic and absolutely hopeless case, the benefit of the provisional treatment order for six months, provided he be treated "with a view to recovery."

#### *The Provisional Treatment Order*

After a patient has been treated under a provisional treatment order for six months and is not likely to recover soon, and in obviously incurable and chronic cases, full certification of insanity and a reception order is a procedure to which no objection can be taken, seeing that custodial and not remedial treatment is its main object. If a patient under a provisional order has not recovered within six months, but is expected to recover soon, it should be possible, with the approval of the Board of Control or other competent authority, to extend the duration of the provisional order to a year, or even longer.

We note, with profound regret, that the justice, a layman, must intervene personally in order that temporary medical treatment may be obtained under the provisional treatment order. Quasi-medical duties and responsibilities are also imposed upon him. Such a recommendation is astonishing in a report that records no case of improper detention and that breathes medical aspirations and professes therapeutic and preventive ideals on almost every page. It is clear from the evidence submitted to the Commission that unmedical legal procedures have in the past been the chief impediment to early treatment and have prohibited preventive measures altogether. The treatment to be given under the provisional treatment order is only temporary and is essentially remedial, it is quite different from that given under the reception order, which is unlimited and is predominantly custodial. There is therefore less reason for judicial intervention in the provisional treatment order than in the reception order, and this intervention would be still less necessary if two medical men were consulted instead of one.

The judicial authority, we are told, is employed for two reasons. First, as a safeguard against improper detention, and secondly, because it is a principle of English law that the liberty of the subject may not be infringed without the intervention of some judicial authority.

With regard to the first reason—namely, as a safeguard against improper detention—if improper detention ever happens it is never the result of malicious intention. So long as human nature remains as it is, and circumstances seem to conspire, mistakes may occur, but when we recall that miscarriages of justice, such as the Adolph Beck and the Ldalg cases, have occurred even in our courts of law, and that no cases comparable to them have occurred in our mental hospitals, then it must be admitted that the record of the medical profession is beyond all praise and one to be proud of. Further, when we consider that in Scotland for seventy years thousands of insane persons have been placed in mental hospitals without being seen by any magistrate, and that no case of improper detention has ever been found in our courts, it is clear that the honour and vigilance of the medical profession are no mean safeguards.

There is another safeguard not judicial, the value of which the Royal Commission does not appear to have realized—the medical appeal. The subject is in Scotland safeguarded against improper detention in an asylum,

and his liberty made almost impregnable, by the right of appeal to two independent doctors for examination. The judicial authority is the sheriff, whose strictly legal functions will be described later. He considers in private the written medical evidence only and makes no quasi medical investigations himself, nor does he invade the privacy of the sick room. His reception order is given wholly on the written opinions expressed by the two medical men first called in, but complete and speedy protection is afforded the patient should these two have made a mistake, by the right of appeal to two independent doctors for examination. This right is enjoyed by the patient, by any relative by any friend by the sheriff and by the General Board of Control, so the machinery can be easily set in motion and in minor ways. A patient is detained in a mental hospital on the certificates of two doctors, and what two medical men have done two others can undo if wrong has been done or a mistake has been made. If the first opinions are confirmed by thus independent and unbiased testimony the opposition of all it is usable persons is silenced. No human or judge or committee not even the General Board of Control itself can act independently of the opinions of the two independent medical men who form the supreme and, for the time being, the final court of appeal. We thus have in Scotland a purely medical system that affords complete protection, that has stood the test of time and that satisfies public opinion. The personal intervention of a justice is therefore not necessary as a safeguard against improper detention if this tribunal exists. An appeal is not made often and obviously frivolous appeals are discouraged by the authorities. In Scotland a sum of £30 a year apparently suffices for the payment of those cases in which no other funds are available.

In the second place, it is stated that it is a principle of English law that the liberty of the subject may not be infringed without the intervention of some judicial authority.

#### *The Judicial Authority*

The object of the lunacy law is to authorize violations of personal freedom for the benefit of the patient and others under certain circumstances and formalities. Between 1845 and 1890 we were informed, on the authority of Dr J C Bucknill Lord Chancellor's Visitor that

any one of the Queen's subjects may be deprived of his liberty captured, confined and detained by the proprietor of a licensed house or his servants, upon the order of any person whatsoever either a British subject or an alien either an adult or an infant either a relative or a stranger either an equal in social rank or a mental substitute the only condition being that he has been the alleged lunatic within one month of making the Order and is supported by the certificates of two men qualified to practice and practising the medical profession.

In spite of this abundance of any judicial authority the Select Committee appointed in 1877 to inquire into the subject of improper detention under the law of 1845 reports. Assuming that the strongest cases against the present system were brought before them, allegations of mala fides or of serious abuses were not substantiated. "It would therefore seem that the infringement of the liberty of the subject without the intervention of a judicial authority is not without ample and striking precedent in the domain of mental disease, and that it was freely practised in England for forty five years without the occurrence of serious abuses. It is still practised in Ireland without abuses arising."

Judicial intervention is not desired by the sick patient nor by his distressed relatives. It is quite alien to medical feeling. It creates difficulties, it adds complications and it causes delay at a time of great trouble and unhappiness. If there must be some form of judicial intervention, then the Scottish procedure has much to recommend it. It preserves the integrity of the medical ideal it respects the sanctity of the home, and it introduces the judicial element in a purely legal capacity. The sheriff, who signs the reception order, is an experienced barrister and a salaried judge. He never sees the patient, he does not make any quasi medical examination. The application and medical certificates are presented to him, and if these be in order and if the facts observed by the doctors indicating insanity

satisfy him, he invariably signs the order. No one could discharge these duties better than this highly trained official; no legal intervention could be less objectionable than the one he follows. Yet the question arises: Is judicial intervention necessary?

Judicial intervention in Scotland is quite superfluous. The inspection of the application to see that everything is in order and the examination of the medical certificates to discover if they truly indicate insanity, which is all that the sheriff does, are in every case as carefully performed by the General Board of Control as by the sheriff. If an order must be signed by a fourth party there is no reason why it should not be signed by the General Board of Control and the sheriff allowed to drop out altogether. The sheriff is only a fifth wheel to the coach. It is more appropriate that a permanent body that has medical as well as legal member on its staff, that is competent to examine patients as well as to scrutinize legal documents and weigh written evidence, should perform the duty of signing the order. This was the view held at one time by the General Board of Lunacy of Scotland, and the Royal Commission contemplates that ultimately it may be that the participation of a magistrate will no longer be considered necessary.

Let us now dramatize the procedure which has been recommended by the Royal Commission before a sick man can obtain medical treatment for his illness. The proceedings are not medical, for a layman is the presiding authority. The stage on which they are enacted is a distracted household for nothing upsets a family so much not even excepting death as the occurrence of insanity in one of its members. Their only consolation is the comforting and encouraging words of the family doctor. The application is signed, not without perturbation the recommendation filled in and now word is hurriedly sent to the justice. Within seven days this strange official, who is not a doctor, comes to interview the sick patient. He is recommended to visit the patient in the patient's own home, and this in the country, involves an expedition. His medical examination is to be no perfunctory performance as was so often the case in the past. As the justices who have a natural or acquired gift for this delicate duty are so selected it may be assumed without offence that all do not possess the necessary accomplishments. Then the relatives are to be interviewed and if this be judicially done both those 'for' and those 'against.' The kinsmen of patients are often trying and some are to be met who refuse ever to see any sign of insanity because if they do there has never been any in their family. If they go he is in doubt he is to confer with the doctor so he is well as the relatives have to put their time at the disposal of the justice however inconvenient this may be to all of them. More than one visit may be considered necessary.

The justice is now to exercise what has been described as a directed discretion. For example, if delusions have been alleged he may deem it necessary to investigate these further, and how much further affidavits may take him no one can tell. All sorts of inquiries may have to be set on foot and many witnesses interviewed. Then he has to decide whether the patient is to be informed of the allegations. To experts this is perhaps not a difficult decision to make—but how often has one been asked by perplexed layman "Doctor, should I agree with everything he says and if I contradict him will he get excited?" This layman has in addition, two medical problems placed upon him which he must solve by a personal examination and by his own discretion. He has to decide first: Is the patient insane or not? And secondly, Is insane as he going to recover within months or not? How a layman without any medical training or experience can answer the latter question is impossible to conceive. If he has to rely on the doctor's opinions and is guided by him, why bring him on to the stage at all? We will here drop the curtain on the first act of this drama.

The second act opens after an interval of six months. The patient has not recovered and the question of placing him under a reception order has to be considered. Two doctors are now called in to assist and give certificates of insanity. The justice may now have the assistance of a

clerk to the justices. The patient may now appoint someone to represent his interests, and there is nothing to prevent him employing a solicitor whom he has found amenable to his instructions. The court is thus carefully and fully prepared for a formal hearing of the case, but the adoption of a forensic procedure is deprecated by the Commission. Apparently those who conduct these medico-legal proceedings are advised to drop, so far as they possibly can, judicial ceremonial ways and adopt the less alarming methods of the medical man in their place. The justice requires to see and examine the patient again, but no instructions are given as to whether the patient is to be present at this "trial" or not. If the solicitor, to earn his fee honourably, defends his client the patient can hardly with justice be excluded from the proceedings during all the time. Nor can the solicitor be denied such access and such facilities of getting up his client's case as he considers necessary, and thus almost certainly would involve the evidence of other patients. Lively scenes, it may be surmised, will sometimes occur. Responsible allegations will at times be flung about, and the Commissioners have very wisely recommended that all parties must be sworn to secrecy. But there is one tongue over which they have no control, and possibly not even its owner can curb it—the tongue of the patient. We know how fond manic patients are of revelling in scandalous and intimate disclosures, and how they love to pose before an audience.

It may be said that the picture here presented is overdrawn, but the more nearly judicial intervention is judicial in character the truer will the picture be to what will occur. The perfunctory way in which these duties were sometimes performed in the past, as by one-minute interviews in lavatories, may possibly have been a saving grace. It is a pity that such disclosures did not lead logically to the abolition of judicial intervention, instead of to its reinforcement and rehabilitation.

Whether non-existent, as between 1845 and 1890, whether performed perfunctorily, as was so often the case in England, or whether performed in the purely legal way without seeing the patient, as in Scotland, judicial intervention or non-intervention seems to have made little difference one way or another, and neither Select Committee or Royal Commission has found any person improperly detained in our mental hospitals. It is clear that adequate protection exists and is afforded by other means. To us in Scotland, who have never had any experience of the personal intervention of a layman, this form of amateur medicine seems a monstrous and intolerable invasion of the sphere of the physician, and nothing less than a caricature and a mockery of medical science and practice. The reason why the medical profession in England has acquiesced in it has been the hope that the personal intervention of the justice would relieve medical men of some responsibility and reduce or abolish the risk of legal actions. That hope has not been fulfilled, although, according to Mr Justice McCordie, the medical certificate was no more than a mere opinion, devoid in itself of operative force, and the reception order was the effective authority.

#### Some Conclusions

The provisional treatment order forms the most striking departure from precedent of all the recommendations contained in the Report of the Royal Commission. Voluntary treatment has existed for a long time, and no facilities are offered that are not already enjoyed in Scotland, where certifiable as well as rate-aided patients can be treated voluntarily. The emergency or urgency order has always existed, but it has been greatly improved by not requiring a statement to the effect that the patient is insane. The provisional treatment order is the offspring of Schedule G of Scotland, but it is a much greater concession, for Schedule G applies only to private patients. The Mental Treatment Bill associated together in one clause somewhat incongruously, voluntary patients and patients without volition but non-resistant, and it was, of course, very desirable that special provisions should be made for the latter class. The provisional treatment order has done much more, for it has conferred the privileges it contains

not only on patients of the class referred to, but also on volitional but resistant patients, provided they are deemed recoverable in six months' time. In effect, these privileges will apply to practically all cases of recoverable insanity. A greater boon cannot be expected of the legislature, and for it we have reason to be grateful to the Royal Commission. Its benefits will be much diminished, however, by the conditions under which they are to be conferred, and as we desire to see these faults removed, the five following recommendations are made.

1 In the first place, we consider that two doctors should be required to give recommendations instead of one only. If the safeguarding of the liberty of the subject be so important a matter, the employment of two doctors instead of one should be acceptable. The power conferred by the provisional treatment order, although of limited duration, is great, and we think it should not be put into the hands of one medical man, even though a justice also sees the patient.

2 Secondly, as a further safeguard to the liberty of the subject, we recommend the right of appeal to be examined by two independent doctors. We believe this privilege will render improper detention almost impossible, as it has done in Scotland.

3 Thirdly, the employment of a second medical man and the right of appeal to two independent doctors, we believe, make it unnecessary for the judicial authority to visit and see the patient. In support of this we point to the results of seventy years' experience of this procedure in Scotland and think it conclusive. The visitation by the justice perpetuates those legal formalities that have in the past delayed treatment, blighted attempts at prevention, and differentiated mental disorders from other illnesses—all grave faults to overcome which were among the chief aims of the Commission.

4 Fourthly, we recommend that the justice be replaced by the Board of Control. It is a strong medico-legal body accustomed to visit patients, familiar with the requirements of the law, and continually engaged already as a part of its duties, in scrutinizing applications and medical certificates. Its task would be analogous to that performed at present by the sheriff in Scotland, which has proved very satisfactory, although he never sees the patient.

5 Finally, as prognosis and forecasting the date of recovery is difficult and uncertain, the conditions required for coming under the provisional treatment order should be altered to those of Schedule G—namely, that the malady is not confirmed and that the treatment to be given is with a view to recovery. This change would make no difference to the patients who would benefit, but it would confer a grateful relief to the physician.

When the remedial stage of the treatment of an insane person passes into the custodial, and the liberty of the subject, as distinct from his curative treatment, becomes the main question, no medical man can object to the adoption of such legal procedures as are considered necessary. It is again affirmed, in conclusion, that the right of appeal to be examined by two independent medical men is a more logical and perfect protection against improper detention than any form of personal intervention by a layman. It has proved a medico-legal panacea in Scotland for all problems dealing with the liberty of the subject in the treatment of mental disease.

#### DISCUSSION

Dr E. MUDSLEY (Maudsley Hospital, London) considered that the Report of the Royal Commission was disappointing. It was to a large extent devoted to the prevention of non-existent abuses, and that in a rather inconsistent way. A great many of the recommendations were matters within the ordinary province of the Board of Control. He could not accept Professor Robertson's clear-cut distinction between the voluntary and involuntary cases, and added that there was a third class of great importance, which included most of the recoverable cases. At the Maudsley Hospital, where voluntary cases were treated, it was assumed that if a patient had voluntarily placed himself under control and subsequently passed into a state in which he was not unwilling, but incapable of expressing his opinion, the consent to treatment which he gave

originally still hold good, the Royal Commission, however, recommended that such a patient should be put under a provisional order. What was a provisional order under the new regulations except a certificate? Some method of dealing with the unwilling case other than by certification was needed—some method of treating such a case outside the asylum temporarily, and some order which was distinguishable from a certificate and did not involve the intervention of a magistrate. One of the many points of detail in which the provisional order or certificate seemed open to criticism was that a patient must be seen by a magistrate within seven days. A doctor might have to wait seven days before getting his patient seen by a magistrate and that would tend to drive him in most cases to the use of the urgency order. The doctor's responsibility when he signed an urgency order was rather different from that involved in signing one of the certificates in support of a provisional order. He was in favour of having special certifying medical men for the giving of a certificate in connexion with a provisional order. In the Commissioners' report this was mentioned as an optional proposal, it was not made a definite recommendation. At the termination of validity of the provisional order, and when the order was to be followed by a definite reception order, the Commission stated that the patient should have the right to claim the attendance of any one person chosen by himself, and that the justice could be assisted by his clerk, elsewhere it was stated that the justice might call upon the medical man to justify his certificate. Dr Mapother objected to the institution of a sort of trial before the patient was committed to a mental hospital in this procedure the patient, but not the medical man, might be represented by counsel.

Dr T B HAYES (London), whilst most heartily approving the Report of the Royal Commission and Professor Robertson's paper, doubted whether the new proposals would get to the bedrock of the troubles existing in England. The first duty of the medical man was towards his patient the second towards the community and the third to himself. To certify that a person was of unsound mind not only deprived him of his liberty and his social, economic, and civil rights but branded him with a label which was borne by his relatives and descendants as well as by himself. The insanity might have been due to bodily causes, such as defects in the internal secretions, in metabolism, in exertions or to toxins and it behoved all medical men to consider whether they were to label their patients as coming within the mental or the physical category. Intervention of the judicial authority had not been entirely successful, either from the point of view of the liberty of the subject or the safety of the certifying practitioner. Both the patient and the medical man should be afforded a sporting chance of the former's recovery without deprivation of liberty. In his opinion the whole question was of such urgency and importance that he hoped there would not be unnecessary delay in bringing into effect the recommendations of the Royal Commission. In the meantime the community must suffer from the inadequate provisions for its welfare.

Dr W I MENZIES (medical superintendent Staffordshire Mental Hospital) deplored the decision of the Royal Commission to decline to recognize the non volitional class of case. The suggested procedure involved three successive personal examinations of the patient by the judicial authority this was impossible in practice. Justices could not give up one day a week to lunacy matters, certainly in any country district in England nor could a dozen or more private medical practitioners leave their work and travel ten or twenty miles to the institution where the patient was placed, and wait about for a half-day until the case came on. Two medical certificates one by the family doctor, the other by a medical officer of the institution, should be placed before the management committee at its monthly or weekly meeting and it should be given *ad hoc* the powers of a judicial authority specially appointed under the Act. The vast bulk of the population were not apprehensive of improper detention, the whole agitation was fomented by a noisy minority, many of them unrecovered patients.

Dr PIERRE PIERRE (London) said that if England enjoyed the privileges available in Scotland for the treatment of mental disorder it would be content. The law for England and Wales ought to be altered to allow patients so affected being treated for at least a year without interference by the law, and certificates ought to be the last resort. As the law now stood in England and Wales treatment was constantly hampered by the ever present fear of conflict with the law and the general practitioner was even more perplexed. Two distinct issues were engaging the attention of the profession and the public at the present time (1) whether the doctor should have the whole 'say' in the matter of certification of a person supposed to be of unsound mind without legal intervention, (2) whether the doctor who certified a person as of unsound mind should be made immune against the possibility of a civil action for damages in a court of law for alleged wrongful certification. When the question was merely one relating to the treatment of a patient the profession was well within its rights in claiming to be the proper judges of what was required. When, however, it became a question of depriving an individual of his civil rights, the matter passed out of the sole province of medicine and became a legal one. The profession was fully justified in claiming protection against civil actions for damages in respect of alleged wrongful certification, but it could only reasonably hope to secure this protection if it was prepared to accept the interposition of a legal authority on whom the whole responsibility must fall. Moreover, if medical men were to expect the protection they claimed, it would seem to be reasonable that they must be prepared in conformity with all other instances in which they were called upon to give evidence, to do so on oath. Even in so comparatively unimportant a matter as whether a man was drunk or sober, a doctor's certificate was not enough but had to be supported in the witness-box. How much more should evidence on oath be required where the decision carried with it such grave consequences to the individual concerned and his family? A lasting damage was inflicted which might have far reaching consequences on other members of the family in respect to marriage life insurance and other matters. The suggestion that there should be the intervention of a representative of the law who must in all instances personally see and examine the person supposed to be of unsound mind did not carry with it the need for publicity, for the person in question need not appear in open court. It had been suggested that the legal representative should be a man trained both in medicine and law and that there were probably a sufficient number of barristers with medical training to fill these posts. This seemed reasonable, but it might leave the matter too "medical" and the question should be viewed from different standpoints hence the importance of having as justice a man with no medical training. The welfare of a patient might be a purely medical question but his safety or that of the public was also a matter for lawyers. Important recommendations by the Royal Commission in regard to such inquiries were that the judicial authority should always see the patient that the person whose case was being investigated should be at liberty to have a friend present and that the justice should be called upon further to exercise what was termed a "directed discretion" which meant that he must consider and state his decision on the issue of his order and whether the allegation with regard to insanity were proved, whether it had been the doctor or and whether the patient should be told of the allegation. The most important recommendation of the Commission in the interest of the patient was that which would allow of treatment without certification for at least a month and possibly six months. How the urgency order was abused in many instances and made use of as a convenience in cases of being strictly reserved for cases of real urgency had been so strongly brought out by evidence before the Commission that the provision for the interposition of a magistrate before the person was sent to an asylum was justified even in the case of an urgency order. The profession should welcome anything that would offer the public a sense of security in these matters so long as that was guaranteed did not conflict with what was necessary for the good of

the patient. That one of the two medical certificates should be supplied by a doctor who possessed special knowledge of mental diseases was reasonable in the highest degree, if found practicable, he saw no objection to having doctors specially appointed under the Act to fulfil this function. In suggesting a way out of the present difficulties a threefold object should be kept in view—namely, to do what was best for the patient, what was acceptable to the public in conformity with the law, and what would give full protection to the doctor. The medical profession should try to find a reasonable solution that would fulfil these three objects. Dr Russell, in conclusion, made a few suggestions as to how these three requirements would be best met: (1) that there should always be two doctors supplying the evidence, except in the very rare event of a case being of such urgency as to make this impracticable, and that one of these medical men should have special knowledge of mental diseases, (2) that the judicial authority should, in every case, see and examine the person supposed to be of unsound mind, and see also the doctors, (3) that in order to secure protection against civil actions, the doctors should give their evidence on oath, and be subjected to cross-examination like any other witness. What was of paramount importance was that medical men should be allowed to treat their patients who were mentally afflicted, without certification, away from asylums for six months at least, and, if possible, twelve

Dr DONALD ROSS (medical superintendent, Argyll and Bute Asylum) described the simple way in which some of the problems so pressing in this country were dealt with in the Canton du Valais, in Switzerland. In that canton there was a most admirable mental hospital, the Maison de Sante de Maleroz. Dr Repond, the physician-superintendent, had said to him, "Thanks be to Heaven, we have no lunacy laws, no inspectors, no boards of control." This last was, of course, their loss, for in Scotland, at least, the General Board of Control was the ever-helpful comforter and friend of the profession. In Valais there was a very simple and workable code of rules for the guidance of the superintendent, drawn up by a former superintendent in collaboration with one of the members of the Cantonal Legislative Council. The admission and discharge of a patient was governed by the superintendent's opinion of the stability of the case. If a patient, though not recovered, was sufficiently improved to go home, but the relatives were unwilling to take him out, the relatives were asked to pay a much higher rate of board, and this was usually quite effective. Dr Risien Russell had spoken of the desirability of having specially trained physicians appointed as certifying physicians in lunacy. One of the speaker's recovered patients, from whom he had learnt much wisdom, always maintained that two medical certificates were desirable, and that while one should be, if possible, by the family physician—as all would agree—the second should be signed by a medical officer in a mental hospital, because, broadly speaking, he alone had the proper experience for the task.

EARL RUSSELL (a member of the Royal Commission) said that the Commission had the advantage of hearing evidence from Dr Robertson, by which it was much impressed, and it had also much admired the system he was able to administer. The Section must not think he undervalued the medical point of view, but when dealing with legislation and amendments to the law it was useless to discuss the matter purely from that aspect. Account must be taken of the attitude of the public—a thing a little overlooked in Professor Robertson's paper, but the Royal Commission had to bear it in mind. There were members on the Commission who held to some extent what he must call the antimedical view, and, whether it was still the effect of Charles Reade's book or not, there did exist in England, among the great mass of the population, a certain amount of suspicion of doctors, particularly of doctors in connexion with cases of insanity. The attitude of the House of Commons had to be remembered. That assembly, represented, not only the intelligence, but the stupidity and the prejudices of the people. The duty of the Royal Commission, among other things, was not to consider merely the

procedure for certification, important as that was, but also the happiness and well-being of that large body of patients who spent years under institutional treatment, regard had to be paid both to their comfort and their feelings—for example, in such matters as the sending out of letters to their friends under conditions of comparative privacy. Certification, of course, was an extraordinarily difficult question. He thought that many of them (presumably he was speaking of members of the Commission) would have been perfectly satisfied with the opinion, certainly of two medical men, if not in many cases of one medical man, but they had to consider the prejudices of the public, and the public's point of view was that the medical man was a poison who was only too ready to certify, and without reason. The fact that the one object of the doctor was the treatment and benefit of his patient was not recognized in that simple form by the general public, which desired the intervention of a magistrate or some other judicial authority, who represented what they called the liberty of the subject. If the judicial authority could be dispensed with things would, no doubt, go on perfectly well, the real safeguard for patients in England was the Board of Control, which consisted of well informed people with ample powers and opportunities of inspection and control, who could perfectly well put an end to any improper detention. They were really of very much more use than any judicial authority. He regarded the suggestion made by Dr Menzies that members of the mental hospital committee should be appointed the judicial authority as absolutely fatal. It would add to the suspicion already entertained that they were "all in the same gang." What was wanted was to satisfy someone from outside who was independent. He thought it undesirable also that the justice should be a poison with medical knowledge. It was not the business of the justice to form a medical opinion, and it ought not to be his business. He had to consider the medical opinions which had been formed by competent people, and it was not for the justice to say from an entirely imperfect and incompetent medical diagnosis of his own whether a patient was sane or not. All he had to ensure was that care had been taken and the thing was in order. When the Commission referred to the "directed discretion" of the justice it rather meant that there were certain matters to which the justice ought to direct his attention as a matter of course in every examination he made and every certificate he gave—that is to say, he should not be left at large to perform his duties in a slovenly manner. The objections to anything like a public trial had been pointed out. There were the gravest objections to a public or a private trial in the ordinary forensic sense of the word. But the Commission received the strongest representations from those who claimed to speak on behalf of patients and ex-patients that they did desire, at some stage or other, to state their case. It was well known, of course, that the prisoner would state his case with great volubility, and it would not further matters, but it was felt that the less the proceedings took the form of anything like a forensic contest the better. It had been suggested that the voluntary patient should continue to be treated as a man who had no volition at all. That might be a lawyer's point of view, but when it was said that a man was doing a thing voluntarily it carried a certain obvious meaning, and a man was not doing a thing voluntarily if he did not know that he was doing it. If voluntary treatment was to be made really successful the public must not be frightened into it. It was true that a voluntary patient would have moments of rebellion, in which he would say he was not going to stand it any longer, and it was to meet those moments that a delay of seventy-two hours was suggested. If voluntary patients were to continue to be treated as such when they became non-voluntary the advantages of the voluntary system would be destroyed. He would be very glad if public opinion in England would allow much greater freedom in the treatment of the insane, certainly that would be to the advantage of the insane, but the prejudice of which he had spoken had to be remembered. If any contribution were to be made to legislation, when it came—and he agreed that there was no chance of it this year, and he feared no chance of it next year—this

prejudice would have to be reckoned with and improvements would have to be sought in a way which would not leave the medical man with complete control. With regard to the urgency order, it had been suggested that justices should always intervene before the patient was removed to an asylum. It was obvious that it was not always possible to wait for the justice to intervene before the patient was restrained. The patient in some cases had to be restrained instantly. The liberty of the subject was maintained by the provision that a doctor or justice must see the patient within three days, but instant restraint might have to be applied. He was rather of opinion that the urgency order was employed where it often was not necessary, and it was very important that the urgency order should not be abused, otherwise it might not be available for cases where it was properly wanted.

SIR DAVID DREMMOND (also a member of the Commission) said that Lord Russell had fully and admirably expressed his own view. It had been a great pleasure to him that the Report of the Royal Commission had been on the whole so well received by bodies of professional opinion, but he was sorry the Commission had found itself unable to safeguard the position of the medical practitioner more than it had done in that report.

SIR FREDERICK WILLIS (Chairman, Board of Control, England and Wales) said that some scepticism had been expressed as to whether legislation was really in view, but he happened to know that the Government was quite seriously considering the matter, and the Minister of Health was anxious, during his term of office, to pass a new lunacy law. In view of this, he particularly welcomed the present discussion, which would be of assistance in formulating proposals or a memorandum for the Ministry. Politicians were necessarily governed by public opinion in these matters, and a Minister might well hesitate to put forward what seemed to him and his advisers the best course if he knew that owing to the attitude of the public it would be rendered impracticable to carry out. The public were still very superstitious, and to some extent had not got away from the view of lunacy which was held a hundred years ago. He was anxious to avoid all formalities in the treatment of the insane so far as this could be done, but though these legal formalities deterred people from getting treatment, this was not the whole deterrent. They were deterred also by the fear lest, should they once consult someone for mental illness, they might be locked up for the rest of their lives. The Royal Commission divided patients into two classes—the voluntary and involuntary. As to the voluntary there was nothing to be said. The Commission had recommended what a good many had urged for years—complete freedom. The Board of Control felt that patients ought to be divided into three classes—the voluntary, the involuntary, and the unwilling. The ground for this was the well known fact that people did not come sufficiently early for treatment. Indeed, under the lunacy law, the rate aided case could not get treatment at all at the public expense until after certification. One of the proposals in the new Lunacy Bill would be to give lunacy authorities perfect liberty to arrange for early treatment, and, if the case was voluntary, without any justice coming in at all. He thought the Royal Commission might have gone even further in this direction, and so have done much to educate public opinion in regard to the early case. In his view adequate safeguards were forthcoming without the justice, the only reason for bringing in the justice was because the public believed that it was a measure of protection. The Board of Control recommended that involuntary patients in need of early treatment should be received in institutions or homes which the Board had previously approved as suitable places for giving such treatment, and that the Board should be immediately informed of the reception of such cases and should have a right to visit the institution from time to time wherever it was thought necessary. Such safeguards, he thought would be quite adequate. Under the present arrangement, he spoke as one who had seen a good deal of the work of the justices in connexion with this matter—

he could not help thinking that there were no safeguards at all in a very large number of cases. If the safeguards were adequate to the treatment of the cases he did not see why the treatment need necessarily be hurried to six months as the Royal Commission recommended. Many of these cases ran for eighteen months or two years. Why, if they were under proper treatment with proper safeguards, should they not be allowed to remain on for that period? He did not quite see why any limit of time was needed. Another point which was exercising the minds of the Board was, What further protection should be given to the doctors? He had been very much distressed over some of the cases that had come recently into the courts. He could not help thinking that the jury, in England at least, was an absolutely unsuitable tribunal to test cases of this character. There was a notorious case in which, after a lapse of about twelve years, a trial took place lasting three weeks. Right through the trial it was obvious that the jury were in great sympathy with the patient—they were always against the doctor—and they decided that, twelve years ago, when the patient was certified, he was not insane. It seemed to the speaker rather absurd, and he hoped that some really constructive suggestions might be forthcoming with regard to that. His own feeling was that that sort of question should be taken out of the province of juries. If it were left to the judges of the High Court much greater justice would be done. In these cases it was usual for "experts" to come in and it had been rather distressing to see the sort of evidence given by one doctor against another doctor. He wished the British Medical Association or the Royal Medico-Psychological Association would make some suggestions on this matter. On the question whether there should be two certificates, or one, there was a financial consideration—namely, that in England it would cost £20,000 a year more to have two certificates for the rate-aided cases instead of one certificate. This was not an indifferent sum, it would be another matter if the safeguard was proved to be necessary, but no case was brought before the Royal Commission in which wrongful detention was established. The only purpose of the two certificates was to satisfy public sentiment. In conclusion, he felt that it was extremely important that all should do what they could to break down the superstition which existed in regard to mental illness. That was the rock on which the ship foundered every time.

SIR ARTHUR ROSE (Chairman, Board of Control, Scotland) confessed himself a wholehearted admirer of the findings of the Royal Commission. He looked upon the report as a very valuable strategical contribution to this great subject. When he and Dr. Marr gave evidence before the Commission he gathered, from the questions asked, that there might easily be a very marked divergence of opinion among the Commissioners and he was immensely relieved and somewhat surprised to find that the report of the Commission was unanimous. The reason for that unanimity was probably that the Commission went only so far as it was believed the public was likely to accept. If a more progressive view had been advanced there would have been a risk of a minority report, and possibly a somewhat strong report, which would have done much to retard any progressive legislation. He urged that any legislation which was proposed should be considered sympathetically by medical bodies, and he did so to a certain extent with a selfish object in view. In Scotland certain amending legislation was required and while he saw no possible chance of Scotland going forward with an amending Act of its own, he was very hopeful that if a reasonably progressive measure were passed in England Scotland would be able to follow, not necessarily adopting the same measure, but perhaps going a stage further than England would have gone.

Dr. C. O. HAWTHORNE said that he had no title to speak on this matter as an expert in lunacy administration, but he happened to have been a member of the committee appointed by the British Medical Association to prepare the Memorandum of Evidence submitted to the Royal Commission and subsequently to examine the Commission's report. What he had to say was without prejudice to

hoped, as well as without intimate personal experience of the carrying out in actual practice of the provisions of the lunacy law. It was therefore with considerable sympathy as well as pleasure that he had heard the speech of Lord Russell, who had brought the discussion down from a somewhat academic level to the actual and practical situation. He had learned, in studying this subject under such conditions as he had defined, that certain broad views had to be considered in dealing with the situation. The first which impressed itself upon him was the severe interpretation attached in the public mind to the certification of a patient. This was an aspect of the subject which had to be most carefully considered. It had been suggested that the Board of Control was sufficient, but that Board arrived upon the scene too late. The stigma had already been inflicted by the certificate, even though the certificate was reported in a few days to have been unnecessary. Even looking at it from that narrow and practical point of view, the very serious nature of the step taken in granting a certificate could not but be admitted. A second impression made upon his mind by the studies and inquiries which were incumbent upon him as a member of the Association's committee was the great importance which was attached, at least in England, to the protection of the liberty of the subject. The propositions put by Lord Russell commanded the whole situation so far as legislation was concerned. The third consideration which he had to bear prominently in his mind was the position of doctors throughout the length and breadth of the land in respect to lunacy certification. There was a reluctance to sign certificates, even, in a considerable number of cases, a determination not to sign them. Deeds of partnership between doctors were being drafted one of the conditions in which was that neither partner should sign a lunacy certificate. It might be that this was a stupid view, but when it was said that sentiments widely spread must be respected in practical legislation he claimed that here was a body of sentiment which must be so respected. There were two positions, and only two, which could be logically defended when considering lunacy from the point of view of the doctor's relation thereto on the one hand, and on the other from that of legislation. It was quite a defensible position for doctors to make the claim that mental disorder, like physical disorder, was a medical matter, and that doctors alone were competent judges. That was a position which could be argued, but it involved a process of education of the public which, as had been generally admitted during the discussion, was very far from accomplished. The other position, which was a sound one, was that the State came in and said, "This is a form of medical diagnosis and treatment which invades the liberty of the subject, and we will not allow medical treatment of that kind to be imposed until we are satisfied that such treatment is necessary." When the State had once said that, it was for the State to say what was the legal machinery by which the State itself could be satisfied that this treatment was essential. The State might ask the advice of the profession, but it was for the State to accept the responsibility necessarily imposed upon it when it declared that this was a matter in which medical treatment should not take its normal course until the State was satisfied that it was necessary. His claim was that when the State had once stepped in and assumed authority, the State must at the same time recognize that it assumed responsibility. The doctors might be asked for advice, for their opinion upon the whole situation, or upon the particular case but that was simply a contribution in the shape of evidence towards the solution of what had now been made a legal issue. If that was the true position, then manifestly the doctor ought to have in this issue the immunities which were enjoyed by other witnesses. Dr. Risien Russell had urged that the doctor ought to give not merely a certificate but an opinion under the sanction of an oath. But why did he not do so now? Simply because the representative of the law did not call upon him to do so. Under the existing lunacy law it was competent for the justices to require that everything should be on oath. There was a choice, then, between these two alternatives. Was the medical profession to go to the public with the high academic doctrine that this whole matter was a matter for doctors, or was it going to say,

"No we recognize the intervention of the State for determining whether this treatment ought or ought not to be applied, but the State must accept the responsibility, and must not allow that responsibility, which carries penal consequences, to be imposed upon the shoulders of the medical practitioners who have given you an opinion in the case?"

Dr. C. HUBERT BOND (Commissioner, Board of Control, England and Wales), after remarking how pleasant it was to find that all his colleague Sir Frederick Willis had said appeared to commend itself to the meeting and that in 1884 the Earl of Shaftesbury was still chairman of the Lunacy Commission in England. Mentally he was as alert as ever, and devoting nearly the whole of his energies to the welfare of the insane, but he was in failing bodily health and feeling the weight of fourscore and five years. At that time a section of the public was suffering from what might be called an anxiety neurosis in mass form, manifested by a few of wrongful detention for alleged mental disorder, just in the same way as when the recent Royal Commission was appointed. As a result of the feeling which was so much in evidence a motion was carried in the House of Lords for the institution of a committee of inquiry into the administration of the Lunacy Acts. It was not intended as an attack on the Lunacy Commissioners any more than was the institution of the recent Royal Commission, but the great-hearted Earl was hurt to the quick. He knew and felt the complete integrity of his own department, and he felt also that, to use his own words, "God had manifestly blessed the efforts of the Commission." He wrote also that he had "everything on his side except self-confidence in his own power to meet" what he felt to be a charge, and that "the defence would be perfect in any other hands." He saw in the drift of such an inquiry and in the legislation proposed to follow it, especially in the proposed intervention of a justice (again to use his own words), "the labour, the toils, the anxieties, and the prayers of more than fifty years being in one moment brought to nought." So far as Dr. Bond knew the history of those days, Lord Shaftesbury had the support of each of his colleague Commissioners, legal as well as medical, and of all the leading medical men practising psychological medicine. The depth to which Lord Shaftesbury's emotions were stirred had its echo in the prayer he was not ashamed to record in his diary. "Cist me not off in the time of old age, forsake me not, O Lord, when my strength faileth." No one could read or listen to the recital of that prayer without reverence and respect. To Shaftesbury, though a layman, the proposals, especially the intervention of the justice, were in themselves, and he took the strong step of resigning the chairmanship of the Board of Commissioners. This was in May, 1884, but in June, upon a hitch arising in the setting up of the committee of inquiry, he was induced to withdraw his resignation. Death, however, withdrew him from the fight shortly afterwards. It was at least permissible to speculate whether, had he been spared, and with sufficient bodily powers to play his part in the fight when it did come, the intervention of the justice would ever have been carried. At any rate, injured to the justice, as in a sense were those who worked in England, they could not listen to Professor Robertson's magnificent and noble appeal to their medical instincts without desiring to pause and ask whether it was not too late to relieve the justice of a task for which the majority of justices had no love or even taste. It might be that if the uninformed part of the electorate, whose importance Lord Russell had emphasized, really knew these and other cogent historic facts, knew of the abuses, as found by the Royal Commission and other inquiries, of cases of improper detention, and could hear or would read Professor Robertson's presentation of the medical and medico-legal aspects, they themselves would give a swing to the pendulum in the direction of *Reformatio medicinae*.

Dr. VERNON BRIGGS (Boston, Mass.) said that his excuse for speaking in the discussion was that he had served in Massachusetts as a member of three different boards concerned with mental disease and under three

different political administrations. He was now on the advisory committee of the State Commission of Mental Diseases. He had followed the discussion of this subject in the medical journals of this country, and he was hoping that England would go far beyond what it had been possible to accomplish in the States. He thought that the experience in the States might offer some suggestions towards the solution of the problem here. In the States the medical societies set themselves to educate the public, and had invited the magistrates to give addresses which were followed by discussion in which the medical men represented their side of the question. This had been of great value to the magistrates and indirectly to the public. Another point in the education of the public had been to endeavour to set in its proper and less alarming perspective the hereditary factor in insanity, with the consequence that the people were not so much alarmed or depressed by the notion of hereditary taint as was the case ten years ago. An investigation had been made of 28,000 certified cases in mental hospitals extending over forty-two years, and the hospital records of these cases showed that in only 54 per cent was there an hereditary factor. In other words, a man who had mental disorder was as likely not to have had a tainted ancestry as to have had it. These were facts beyond dispute, and the education of the public along these lines helped to bring about a better state of feeling. With regard to certification, the plan was for two physicians to certify cases which were considered dangerous to the public or to themselves or to need medical treatment. There was such a thing as voluntary commitment, whereby the patient could go into hospital for any length of time, so long as he did not become irresponsible. A system of six months' parole which could be renewed for a further period, was in force for patients who had recovered up to a certain point, and such patients could be, if necessary, returned to the hospital without any further legal procedures. The patients had not to be brought before a magistrate, it was true that the magistrates had a right to send for the patient, or to go and see the patient, but they hardly ever exercised it. Probably 95 per cent of the patients committed were never seen by any magistrate. He could recall only one legal action by a patient against a physician—it was in New York—and though the jury awarded a certain amount of damages, the verdict was afterwards set aside on the ground that certain of the evidence was inadmissible in law. The opposed tactics of medical men relating to the same case in criminal actions had caused some perplexity, and an effort had been made to eliminate such occurrences by discussions. One result had been that in the case of criminals who had been to gaol before and criminals arraigned on a capital charge there was, before trial, an examination by the State Commission of Mental Disease. A law to this effect had now been in force for five years in the State of Massachusetts. The clerk of the criminal court was bound to report the case to the Commissioners of Mental Disease, and the Commission appointed two alienists of standing to examine the alleged criminal. Their report was filed by the clerk of the court, and was open to both sides—the prosecution and the defence. In the five years during which this plan had been in operation there had been no case for trial before the courts in which medical men had appeared against each other in the witness-box, previously it was a constant occurrence. The result had been to raise the position of the profession. He hoped to learn something from this country as to the treatment of the early case. In his own State a sum of £20,000 a year was now being appropriated for clinics to which early cases could be sent. The Legislature felt that the money was well spent because cases might so be prevented from becoming a burden for many years upon the State.

The CHAIRMAN (Dr Marr) said that owing to the lateness of the hour he was now compelled to close the discussion although there were several others who had intimated their desire to speak. Dr MORRIS-BROWN protested against the closing of the discussion, to which, she thought, a whole day might well have been allocated, the voice of the general practitioner had scarcely been heard and the woman's point of view had not been put

forward. The CHAIRMAN said that he regretted very much having to close the discussion, but he pointed to the lateness of the hour and to the fact that the audience was rapidly thinning. He had selected the names of speakers in the order in which they had intimated their desire to speak, except that he had called upon two or three others who, because of their position or work, he thought everyone would wish to hear.

## SECTION OF THE HISTORY OF MEDICINE

JOHN D. COMPTON, B.Sc., M.D., F.R.C.P.E.I., President

### A VINDICATION OF THE SECTION

THE PRESIDENT remarked that this was the first occasion on which a Section of the History of Medicine had been held at an Annual Meeting of the British Medical Association. He had had many letters from persons in this country, on the Continent, and in America, expressing their approval. At the present time no medical school in Great Britain required its students to learn the history of the subject, and there were only a few at which it was possible for the student who desired it to obtain such instruction. This was remarkable in view of the fact that a knowledge of ancient law was necessary for the training of a lawyer, while Church history was considered essential to the theologian. Even in practical sciences like chemistry, physics, and engineering a knowledge of when and by whom the various laws and facts of their sciences had been discovered was regarded as a necessary part of the study of the chemist, the physicist, and the engineer. He would go so far as to say that in connexion with even so common a disease as pneumonia the doctor would be likely to treat his patients more successfully if he knew something about the history of this disease, and if he had some inkling as to why some measures of treatment had been abandoned while others had persisted. The officers of the Section had decided at this first experimental meeting to regard the subject from a practical rather than from what might be called the antiquarian standpoint, and they had accordingly arranged for a discussion on 'The historic evolution of disease.'

### CLINICAL VARIATIONS IN DISEASE FROM THE HISTORICAL POINT OF VIEW

SIR HUMPHRY POLLARD, Bt. K.C.B., M.D. (Fellow Professor of Physics in the University of Cambridge), opened a discussion on this subject by reading the following paper:

This is the first time that a section has been devoted to the History of Medicine and the exertions of our President, who is Lecturer on the History of Medicine in the University, to bring this about in a city with such long traditions in medicine have most appropriately been crowned with success.

A discussion on 'Clinical variations in disease from the historical point of view' is also singularly appropriate in the Northern Athenaeum where it was the subject of much high debate some twenty years ago. W. P. Alison and Robert Christian were convinced that a change in the clinical manifestations of disease had gradually taken place during the first thirty years of the nineteenth century, whereas John Hughes Bennett—who in 1823 succeeded to the Professorship of the Institute of Medicine, and who Alison had held from 1822 to 1823, Allan Thomson intervening, was emphatic in the opposite direction. On January 21st 1857 Hughes Bennett read a paper before the Medico-Chirurgical Society of Edinburgh on 'Observations on the result of an advanced dysentery and pathogenesis applied to the management of intestinal inflammation, compared with the effects of a former antipneumonic treatment, and especially of blood-letting' which aroused much criticism from Alison, T. Watson, and W. T. Gardner, to which Hughes Bennett promptly replied. He concluded that the supposed change from a splenic to a hepatic

type of disease was invented as an afterthought by way of justification for the undoubted change from the more vigorous antiphlogistic measures and venesection to a more supporting and stimulating treatment, and that the change had been in the treatment, not in the disease. Markham adopted the same doctrine, and Hughes Bennett followed this up by a treatise on *The Restorative Treatment of Pneumonia* (1865) which, according to our President, was most effective in banishing excessive venesection as a routine treatment. In 1865 William Stokes strongly supported the change of type in disease, but later Murchison wrote

"A careful study of the history of epidemics shows that each of the continued fevers and of the other acute specific diseases has maintained its identity in all ages and countries. The statements which have been made in reference to fevers having undergone a change of type or nature are mainly to be attributed to a non-recognition of different species, together with changes in the prevailing fashion of treatment."

He instance as an example of this confusion typhus, a fatal disease, with relapsing fever which rarely has a lethal termination. When these two diseases occur together the distinction between them might easily go no further than the view that the type of the prevailing epidemic had altered, in certain circumstances, especially towards the close of an epidemic, when the mortality rate is falling, it may be difficult to decide more particularly from the records, whether there was merely this change or whether a new disease had come on the scene. The comparatively frequent coexistence of two diseases—namely, typhus and bubonic plague—in epidemic form during the sixteenth, seventeenth, and eighteenth centuries, though the nature of typhus was not recognized, is pointed out by Crawford.

#### Sources of Information

The surest, though much limited means of getting reliable knowledge as to the nature of disease in the past is morbid anatomy, which under the name of palaeopathology, defined by M. A. Ruffer (1913) as the "science of diseases which can be demonstrated in human and animal remains of ancient times," has been recently employed, especially in Egypt by Pouquet (1889), M. A. Ruffer, Elliot Smith, and Wood Jones, and in America by R. L. Mordue, who has done much work in the investigation of bone disease in fossil animals in the prehuman ages of 500,000 years ago. Though the diseases that can thus be recognized are mainly those of bone, examination of mummies has shown the existence of osteo-sclerosis, tuberculous disease of bone, mastoid disease, hydrocephalus, rheumatoid arthritis (2000 B.C.), gout, tilipes, dental caries, prothuber, pneumonia and anthracosis of the lungs, hepatic cirrhosis, biliary and urinary calculi, bilharzia, renal abscesses, peritendinitis, and achondroplasia, but not of rickets or syphilis, the appearances ascribed to syphilitic osteitis being really due to the activities of beetles after death (Elliot Smith), thus has a bearing on the much debated origin of syphilis in the old or in the new world.

The account in the *Times* of April 7th, 1927, of the tomb of Senb in the sixth dynasty (2900 B.C.) seems to show that he was an achondroplastic. Professor Elliot Smith, who considers this is much the earliest certain proof of this condition, has put me in touch with Mr. Warren R. Dawson, and I have thus had the advantage of seeing a paper that he is publishing on "Pygmies, dwarfs, and hunchbacks in ancient Egypt," from which the following information may be taken. Pygmies were members of a small-sized race from the interior of Africa, and not as Pierre Marie suggested, achondroplastics, on the other hand, the dwarfs, whom the ancient Egyptians were accustomed to attach to their establishments, were usually people of stunted development, often achondroplastics, drawn from their own population, and of these many examples mainly males, are extant in mural paintings and sculptures. In a Roman cemetery (A.D. 200) at Chester evidence of achondroplasia was found (Elliot). Of acute disease in ancient Egypt there was evidence of an eruption resembling small-pox in a mummy of the twentieth dynasty (1200-1100 B.C.) (Ruffer and Ferguson).

Sculptures and models provide valuable evidence of diseases in the past especially abnormalities of growth,

Egyptian and Greco-Roman sculptures and statuettes definitely show the existence of achondroplasia—for example, the gods Ptah and Bes—and at a much later date pictorial representations of Court attendants by Velasquez and others tell the same tale. Mr. Warren Dawson reproduces ancient Egyptian statuettes showing stertopgia, and Pott's disease of the spine is shown in a bronze statuette of ancient Egypt. Sir Berkeley Moynihan recognized the manifestations of cerebro-spinal fever in a bust done of Alexander the Great in his fatal illness. Votive offerings, although studied by Hollander, Sombon, Regnault, and others, are disappointing as accurate representations of the patients' lesions.

There is not so much information to be obtained from the available pictures of antiquity, but mural paintings in Egyptian tombs of various periods show achondroplastic dwarfs 5,000 years ago (Ruffer), and those from Pompeii and Herculaneum, now in the museum at Naples, represent some pathological conditions, such as achondroplasia and rickets (Meige). The portrait in the Uffizi Gallery, Florence, of Ferdinand I, Emperor of Germany, painted in 1521 by Lucas van Leyden and reproduced by Semon, shows the adenoid face, though it was not till 1868 that Wilhelm Meyer of Copenhagen made adenoids known to the profession. The famous epidemic dancing mania, variously called *le dance de Saint-Guy*, dance of St. John or of St. Anthony, and by Paracelsus *Chorea Sancti Viti* (as pilgrimages were made for cure to the Chapel of St. Vitus at Zibern), so prevalent in the Rhine provinces during the fourteenth and fifteenth centuries and lasting into the sixteenth, was drawn by Pierre Bienghel (1567-1625) and engraved by Hondius in 1642, and thus identified with major hysteria and hystero-epilepsy by Charcot and Richet, who also recognized hystero-epilepsy in Raphael's pictures. In their *Les difformités et les maladies* (1889) these authors reproduced a number of pictures showing plague victims with buboes, and among them Saint Roch (born A.D. 1295), the patron saint of that disease. Paintings may show that at the time they were painted certain diseases were more severe than they are now, and they may represent morbid conditions, such as leprosy, which have now become rare, and of diseases which have now disappeared—such as hydrophobia, described by Aristotle and Galen, the subject of many papers in the medical records of the eighteenth century, and familiar to some of us now present, which has become extinct in this country as the result of the administrative action of the Muzzling Order (1897). As showing the importance of such precautions it may be mentioned that in Moscow six hundred people were recently reported to have been bitten by mad dogs, and to be therefore attending the Pasteur Institute.

The written records of acute diseases, though far more numerous than the pictures and the representations by the plastic artist, are more difficult to utilize in the recognition of disease. Alterations in methods of description and nomenclature interfere with the identification of the nature of bygone epidemics, and the probable existence of more than one disease raging at the same time, as in the Antonine plague in Rome, adds to the difficulty. An example of the difficulty of translating ancient into modern terms is the designation "*lepra*," which covered lupus, syphilis, pellagra, and many skin diseases, as well as leprosy. It is, however, extremely tempting to read into an ancient description of disease that of one more recently recognized.

#### Evolution of Disease

As disease is not a fixed entity but a reaction of the complex organism to varying degrees of injurious influences, it is reasonable to anticipate that with altered conditions in the soil or the host, such as more rapidly and most obviously produced by famine and war, the reactions would vary accordingly, even if the morbid agent remained the same. In addition, changes, extremely slow though they may have been, from the cave to the club man, would suggest that their diseases, like their virtues, would present a somewhat different aspect. Changes in the body organisms responsible for infective disease occur with far greater rapidity and ease than in the higher animals, and hence it is obvious that corresponding modifications in the reactions they set up must be anticipated, even in the soil

remained unaltered. Chapin considers that changes in the virus are much more important than those in the host, and argues that alterations in the type of small-pox and scarlet fever are not due to changes in the immunity of the host. Changes in the type of disease, like epidemics, are readily determined by wars and famines, which lower the bodily resistance, and, by the accompanying overcrowding, increase the opportunities for the transmission and the virulence of infections. These clinical changes would be more likely to occur in acute epidemic diseases than in some chronic and constitutional conditions, but unfortunately it is in the acute epidemic diseases that it is most difficult to judge whether or not real changes have taken place.

Alteration of the clinical manifestations may depend on secondary infections. Influenza in 1918-19, when complicated by *Lactococcus streptococcus* invasion of the respiratory tract, became widely fatal, and its aspect altered so much—as indeed, has been so often seen in its history, as shown by its numerous names—that it was actually hinted in the lay press to be plague. The present mild small pox, or alastrim, has been thought to be due to the specific virus alone and the ordinary more severe small pox to be caused by a secondary streptococcal invasion favoured by the insanitary conditions so prevalent in the past. The influenza virus, whether filter-passing or Pfeiffer's bacillus favours invasion by or sensitizes the tissues to the action of other viruses. The influence of measles in leading to tuberculosis is familiar, and it is possible that carriers of the viruses of encephalitis lethargica and of acute poliomyelitis and the meningococcus, may become infected as the result of influenza infection, or, to express the same result in other words, that the influenza virus may activate latent viruses of encephalitis lethargica, acute poliomyelitis, and cerebrospinal fever.

The problems frequently arise whether changes in the clinical characters of disease are real, such as that universally acknowledged to have occurred in scarlet fever, which was serious and often malignant forty or fifty years ago and now is mild, whether apparent alterations are due to modification in description rather than in fact—in other words whether the change has been in opinion only, and whether more accurate observation has led to subdivision of what were previously regarded as "clinical entities" and so to the crystallization of new diseases, such as typhoid, paratyphoid, and typhus, out of "continued fever" and the various forms of anaemia. It is natural, but futile to speculate how far the evolution of the streptococci can be correlated with the appearance of the numerous diseases now known to be associated with their presence. The tendency of pathologists, bacteriologists, and clinicians has been to separate out specific diseases, whereas that of some epidemiologists, notably Hamer and Crookshank in this country, has been in the opposite direction, and to regard as modifications of a basal disease what are by others regarded as etiologically distinct.

It is natural to assume that with alterations in the seed and the soil the resulting changes in the clinical picture may become so definite as to constitute new diseases, for of course disease must have undergone a gradual process of evolution and may be expected to appear, wax, and wane. The separation of the various exanthematous fevers is a more modern achievement than perhaps many realize, and it is not unlikely, as Chapin suggests that some of them are of comparatively recent development. An eruption like small pox was identified in an Egyptian mummy (1100 B.C.) though, in spite of Rhazes (A.D. 1000) it was not really distinguished from measles until 1675 by Sydenham, measles and scarlet fever, which were not differentiated until twenty years later, now seem distinct enough but there were many acute observers before their differentiation much more recently—in 1881—came German measles (rubella, rotheln) and now there are the much discussed, if not still doubtful, fourth and fifth (erythema infectiosum) diseases. Typhus was probably a famine fever in ancient Greece, but it is impossible to make any statement about the occurrence of typhoid fever in ancient Greece (W. H. S. Jones 1909), and of course typhus and typhoid were not differentiated until the nineteenth century. Chicken pox was not definitely recognized as a distinct disease until the middle of the eighteenth century, by William Heberden

the elder in 1767, and may reasonably be regarded as vaccinia is known to be, as of the same stock as small pox. At the present time the dualists believe that alastrim, or para-small-pox, is distinct from ordinary small-pox, and not merely a mild form of the disease, analogous to the present scarlet fever. It might be urged that in para-small pox the evolution of a new form of disease is occurring, just as in the past German measles (rotheln) has been distinguished from measles and scarlet fever. But the evidence both immunological and clinical, is in favour of the view that it is a mild form of small pox, not a distinct disease and that with vaccinia these two conditions are due to variants of the same virus. Further, history shows that in the past extremely mild epidemics of small pox have occurred (vide Newman).

War and its attendant circumstances may so alter the conditions as to lead to the appearance of new forms of disease, such as trench fever and trench nephritis (also seen seventy years before in North America, but not in the interval), or of diseases rare in ordinary time, such as spirochaetosis icterohaemorrhagica and, from the associated starvation of non-combatants and prisoners, famine oedema and deficiency diseases. In his recent paper on the

"Influenza constitution" Hamer includes typhus in this category, and ascribes its peculiar features and the rash to the influences of famine, remarking that epidemiologically typhus cannot be regarded as a clinical or pathological entity, and correlates the decline in typhus and relapsing fever with the apparent increase in the mortality from influenza and pneumonia. The epidemics and now or unusual types of diseases produced by war and famine tend to disappear or to become rare with the advent of peace and better conditions.

#### The Clinical Recognition of Diseases now Distinct

Though difficult, there is much interest in attempting to determine when present-day diseases were first known, and, what is by no means the same proposition, when they first appeared, for the revelations of palaeopathology may go further back than written records. For if their morbid lesions can be certainly recognized the clinical aspects must have been on much the same lines as at the present time. Tuberculosis has been identified in the Egyptian mummies, and from written records, there is evidence that the pulmonary form was very prevalent in ancient Greece, in spite of the open air life and the supposed antagonism of malaria. Mumps appears to be one of the very few acute infectious diseases accurately isolated in ancient Greece, and with its orebitic complication was described by Hippocrates, bubonic plague is undoubtedly a disease of established antiquity. The pestilence which attacked the Philistines after their capture of the Ark of the Covenant has been conjecturally thought to have been plague, as those who did not die developed tumours and were advised to make offerings of five golden representations or their tumours and of five golden mice. Otherwise the earliest account of the plague, with the diagnostic references to the buboes, have enabled its appearance to be recognized in the third century B.C. in Egypt, Libya, and Syria. Aretaeus (A.D. 70) mentioned pestilential buboes. Its history can be most certainly traced from the great plague of Justinian, which came from Egypt in A.D. 542 and overran Europe. The nature of the plague of Athens (430 B.C.) described by Thucydides and Diodorus Siculus has been thought to be malignant scarlet fever, or small-pox, but typhus has also been confidently suggested by Murchison. The pestilence in Rome in A.D. 165 the Antonine or long plague which was noted by Galen, has been variously identified as dysentery, small pox, and, like the plague of Athens as typhus. There is, as Crawford points out, reason to believe that it was not one and the same disease throughout the fifteen years or its duration.

Malaria has been conclusively shown from contemporary literature of the time which proves the clinical combination of the disease then to its present form, to have been prevalent in Greece from the fourth century B.C. and in Italy from about 200 B.C. W. H. S. Jones (1907) who has most thoroughly correlated the classical references to malaria, shows that there is good reason to believe that one factor in bringing about the decadence of these two

cut powers was the deterioration of national health by malarial infection. His work shows the value of medical history in explaining that of the world.

Although a clinical distinction between *gout* and *rheumatoid arthritis* dates only from the sixteenth century, evidence of chronic arthritis is forthcoming in Neolithic skeletons and in ancient Egypt. Professor Elliot Smith had intended to be here and to have shown that it existed in 4000-3500 B.C. It is interesting to find that from his special study of gout in Byzantium, Jean-Marie has come to the conclusion that of the twenty-four Sultans in the period 1299-1695 six, or one in four, were victims of this disease.

The history of *diphtheria* exemplifies the difficulty of distinguishing between acute infections involving the throat as ordered and identifying them with those now recognized as quite distinct. So much so, indeed, that Adam signified that diphtheria arose as the result of the transformation in special circumstances of a harmless diphtheroid organism into a virulent pathogenic bacillus about the time that P. P. Bretonneau of Tours drew his sharp-cut classical picture of the clinical characters of the disease. Putrid or malignant sore throat had often been described—by Aetius the Cappadocian in the second century A.D., and Aetius of Amida in the sixth century—and it has been thought that the morbus suffocans or garotillo in Spain in 1583-1618, 1630, 1645, and 1660 were epidemics of severe diphtheria. John Fothergill's *Account of the Putrid Sore Throat* (1748) probably dealt with diphtheria as well as scarlet fever, and, as Norman Moore pointed out, John Huxham, in his description of malignant ulcerous sore throat in 1767, mentioned paralysis of the soft palate, and so was dealing with diphtheria, although he did not distinguish it from *scarletina anginosa*. Francis Home's description in 1763 of croup (a word employed by Patrick Blair in 1713) may have been of diphtheria, and certainly gave rise to much confusion, which even now is not unknown in connexion with diphtheria certification. Cullen's *cynanche maligna* may also have been diphtheria. In spite of P. P. Bretonneau's descriptions in 1821 and subsequent years diphtheria was not separated from scarlet fever in this country until the official returns of the Registrar-General for 1855 (published in 1857) when it became a world-wide disease.

#### Influenzal Diseases

The epidemic occurrences of influenza with its attendants in allies or modified phases is a subject of great interest, and has been attractively signed by Hamer, Crookshank, and J. F. C. Nash from the epidemiologist's nearest point of view as against the specializing bacteriological standpoint.

The *swarting sickness*, or sudor anglicus of the sixteenth century is an example of a disease which has been thought to have had its day, though perhaps not to have entirely ceased to be for it has been reported in a modified, certainly milder, form in the Picardy sweat, or *la sueur militaire*, which occurred in 1886 in the Canton of Lucerne-Chateau and proved fatal in 130 out of 1,200 cases (Pierment). And in 1906 in the Charentes when 6,000 persons were attacked with a mortality of about 2 per cent (Henry). The more modern epidemics differed from the early ones in the longer duration of the illness and the outbreak of a military rash on the third and fourth days. Many outbreaks of this curious disease have been recorded, Hirsch collected 194 epidemics in France alone between 1714 and 1874. Its history is of some interest, though called the sudor anglicus it appears highly probable that, whatever its nature, it was brought to England in 1485 from Normandy by Henry VII's mercenaries, who may have been carriers. Pirnie suggested that when introduced into this country it found a virgin soil and so ran like wildfire, just as picasies did in the Feroe Islands (1781 and 1846) and Japan (1875 and 1907). In this country five epidemics

were recorded—in 1485, 1508, 1517, 1523, and the last in 1551. The onset was described as dramatically sudden, sometimes fatal after a few hours or even instantaneously. Crues, who had the opportunity of seeing it in 1551, wrote two brochures on it, one for popular consumption, *Le Role ou Conseil contre le Sueur ou Sweating Sickness* (1552), the first monograph on a single disease in English, and a professional expansion in Latin *De Ephemera Britannica* (1556), and stated that it was "a fever of one natural day." Much able argument has been brought by Hamer to prove that the sweating sickness was really influenza, and Nash and Crookshank have followed his lead, on the other hand, Chantemesse, President of the Commission appointed to investigate the Charentes epidemic, was emphatic that there was not any resemblance between them (M. Foster), and the Commission suggested that it was transmitted by the fleas of field mice.

*Cerebro-spinal fever*, which Hamer regards as one of the influenzal or enteric diseases and "manifestations of one and the same influence," was first formally recognized in 1805.

*Denque*, spread by mosquitos and now regarded as probably due to a filterable virus, has been recognized since 1779. It is a pandemic disease of the tropics, and in some epidemiological respects resembles influenza, in fact, Hamer has persuasively signed that it, like the sweating sickness, is influenza, and in all three claims to "discern the operation of a single disease entity."

*Encephalitis lethargica* when described in 1917 by von Economo of Vienna and seen in the following year in this country appeared to be a new disease. This view was vigorously contested by F. G. Crookshank, who signed that it was the same as acute polio-encephalo-myelitis and one of the influenzal manifestations which could be identified in medical history for at least 400 years, its occurrence being so irregular and at such intervals that it was frequently regarded as "a new disease." Arthur Hall, while inclined to admit that probably the Tubingen *Schlafsucht* of 1712-13, the "noria" in Italy in 1889-90, and some small groups of cases may well be so regarded, points out the danger of leading into the often vague records of past epidemics a description of a disease not named until much later. He, however, recognizes that Dubini's diencephalic cholera in Italy during 1846 and the following years corresponds to what is now known as the myoclonic form of epidemic encephalitis. It may be noted that in 1413 an outbreak of epidemic hiccup, which also appears to be a manifestation of the myoclonic form, occurred in Fontenay (Tillot-Royer).

Some other changes in the incidence of disease may be briefly mentioned. *Appendicitis* has undoubtedly become much commoner since 1889 when influenza broke upon us after an absence of forty-one years, and it might be excusable to connect it in some way with the gastrointestinal form of the epidemic disease but there does not appear to be any historical evidence in favour of this association. That appendicitis existed before Reginald Fitz of Boston baptized it in 1886 is clear from the accounts of James Parkinson (1812), John Burne (1836), Addison (1839) and even earlier isolated cases, such as those described by Vesalius (1759) and Musgraves (1684). For its widespread and frequent incidence in recent times there have been many attempts at explanation, mainly dietetic in character, it does not appear probable that its greater frequency now is apparent rather than real and due to more accurate diagnosis in modern times, for this has taken place under the eyes of those who have watched the declension of chlorosis all over the civilized world, which has also been ascribed to changes in fashions of food or of clothing. Permeiosis (Addisonian) among the other anemias, and the leukemias have almost certainly become more numerous or at least more commonly recognized as a result of intensive microscopic examination of the blood and haemopoietic tissues, thus Niemann's or Pick's disease has been separated from Cushing's splenomegaly.

Environmental factors necessarily have an important influence on the incidence of diseases—for example in parasitic diseases conveyed by animal or insect carriers, such as hydatid (dogs) and malarial (mosquitos) infections.

The history of the word *diphtheria* forms an interesting story in the *Medical Dictionary* and in the *Medical History of Diphtheria* at *Leicester University and London* (1925). Bretonneau originally called it *diphtheria* (from *επιφθέρω*—a membrana) and *επιφθέρω* with its comment on *επιφθέρω* (diphtheria) and *επιφθέρω* (diphtheria) that it is a word of Greek origin and the word *diphtheria* in a letter to Bretonneau as early as 1825 (Tillot).

knowledge. The work to which he wished to refer was a scientific compendium or a popular educator, and its radical interest lay in the fact that after the description of each mineral, plant, or animal an account was given of its medical properties. The medical use of every well known animal was defined, and small animals were administered whole for reduction of stones in the bladder. As regards the historic evolution of disease, what comparisons could be made? Could any conclusions be framed as to which diseases were commonest? It was only possible to say which were most frequently mentioned, and quinine fever occurred most often, probably it was not so common now. Diphtheria, though not now common in tropical countries, was mentioned frequently in this work, and gout was distinguished from acute rheumatism. Hemiplegia was fairly frequently mentioned, as was to be expected, the other common diseases were catarract, stone in the bladder, leprosy, ringworm of the scalp, and tuberculous glands. Here there had probably not been any change

Dr A. A. WARDEN (Cannes, France), after referring to the question whether appendicitis was now more frequent or whether all appendices removed had really been the subject of acute inflammation, asked when appendicitis was first diagnosed and named. He thought the earliest report was that of the case of the French statesman Gambetta in Professor Lannelongue's detailed paper. Gambetta died in what were thought to be very suspicious circumstances. He had been either accidentally or intentionally shot, and in the course of the next few weeks he developed an illness which proved fatal. Professor Lannelongue stated that he diagnosed an appendicular abscess and desired to operate, and all the other consultants refused. The drawings made by Lannelongue at the time were published in the paper, and a photograph was also given of Gambetta's hand, showing that the wound caused by the bullet was completely healed and had not caused his death. This was probably the first definite record of the diagnosis of appendicitis confirmed by *post-mortem* examination, the year being 1881.

Sir STUART THOMSON (London), after praising the inauguration of the Section, quoted Napoleon's remark, "The only guide to the future is the past," and that of Goethe, "The man who looks forward only sees one road of advance, but the man who also looks backwards sees two roads."

Dr WRIGHT (London) said that an understanding of the evolution of disease was very much assisted by the study of the conception of disease through the ages. The present view of the causation of disease was that it was bacterial in its origin. Although the ancients and the medievalists had no knowledge of bacteria, they did attribute disease to putrid or miasmatic morbi, and he thought no stronger evidence could be produced of the fact that disease was attributed to these causes than was to be found in the writings of Lucretius, who summed up the scientific philosophy of his period. In classical and medieval times disease was very closely associated with miasmas, and there, of course, instinct was correct. All sensations were attributed to particulate matters which came from the various effluvia, and it was natural to seek the prevention of disease by counteracting the effect of these miasmas through the introduction of more pleasing odours in the form of aromatics. Sweating sickness had given rise to a great deal of controversy in the past, and the classical and medieval writers largely attributed it to particulate matter. Referring to appendicitis, he said that of course perityphlitis, typhlitis, and appendicitis were all the same disease, it was a very old disease, and was referred to in the earliest medical literature. The English name for it was "the passion," and it was referred to by Sydenham, whose treatment was the application of the warm body of a living puppy to the right iliac fossa. Dr Wright quoted from Heister a description of a dissection, which he thought was probably the first authenticated case of appendicitis as distinct from perityphlitis.

Sir HUMPHRY ROBERTSON, in replying, said that there had been descriptions of appendicitis in England in the seventeenth and eighteenth centuries, and still earlier ones

in Egyptian mummies. Parkinson described it in 1812, Houskirk also described it, and so did Bunce, and these probably inspired Addison's description in 1839 in the first and only volume ever published of Addison and Bright's *Treatise on Medicine*.

## The Sections.

### BRIEF SUMMARY OF PROCEEDINGS

(Concluded from page 174)

#### SECTION OF MEDICINE.

Thursday, July 21st

##### TREATMENT OF ACUTE LOBAR PNEUMONIA

PROFESSOR J. HILL ABRAHAM (Liverpool), Vice-President of the Section, presided over the discussion, which was opened by Professor John Hay (Liverpool), who commented on the lack of unanimity as to the actual nature of acute lobar pneumonia, the drift of opinion now seemed towards the view that it was essentially a local disease striving to become general. The outlook in a particular case depended on the violence and type of the infection and the resistance of the patient. It was, however, a self-limiting disease tending to recover, 75 per cent of cases surviving if allowed to do so. With regard to prophylaxis, much more care should be given to the prevention of contagion than was generally the case, there was no longer any uncertainty as to the value of prophylactic vaccination, as the beneficial results of inoculation had been proved conclusively. The common cause of death was emulsion failure, the important factors being (1) toxæmia, (2) myocarditis, (3) stasis on the right heart, and the essentials in treatment were fresh air and complete physical and mental rest. Professor Hay gave detailed suggestions as to how these were best ensured. Specific treatment consisted of treatment by vaccine or serum or both. Dealing with vaccine treatment, he quoted the opinions of rival schools of thought, and confessed that hitherto his own attitude had been frankly critical, the position was, however, altered if one regarded the disease as essentially a local one in the lungs, and he had been much impressed by the successful results reported by Captain Malone. All advocates agreed that vaccine, to be of any use, must be given within the first three days. With regard to serum treatment, Type 1 serum had made good. Turning to symptomatic treatment, Professor Hay discussed the methods of relieving pain and insomnia, which must be overcome if rest was to be assured, and the need for opiates was emphasized. In the prevention and treatment of cardiac failure the efficiency of the myocardium must be maintained, and oxygen must be administered in an efficient way at the first indication of cyanosis. As a heart stimulant alcohol was not only useless, but detrimental. The routine administration of digitaline he believed to be of definite value and caffeine was a good cardiac stimulant. Strichnine, however, was much overrated, and there was no evidence that it was a direct cardiac stimulant. Professor W. H. Wynn (Birmingham) spoke in favour of the vaccine treatment of acute lobar pneumonia. Many medical men were afraid of giving vaccine for fear of getting a reaction in the negative phase, but a reaction only occurred in sensitized individuals, and the sensitizing antibodies were only present in acute infection after an interval, in this interval vaccines could be given without reaction, and by giving an adequate dose it was possible to control the infection to a large extent. His vaccines were made from young primary cultures, 100 million being the smallest dose for an adult. Charts were shown demonstrating the immediate fall in the temperature if the vaccine was given during the first two or three days. If given later the result was more difficult to obtain and repeated injections might be necessary. Dr H. Moxley Fletcher (London) agreed that once the diagnosis was made the patient must be disturbed as little as possible. He was also in general agreement with regard to alcohol but he thought the pendulum was swinging perhaps too far, and that there was danger in the absolute prohibition of alcohol in pneumonia, as in

certain circumstances it was helpful. Deathermer was worthy of further consideration. In his view oxygen given early, adequately and systematically was the most important therapeutic agent. He had used sodium nucleinate but had seen no good results. Professor P. I. S. McDowall (London) dealt with cardiac failure from the physiological aspect and recommended bleeding as the best physiological method for the relief of the heart. Alcohol reduced venous pressure and thus explained its beneficial action in pneumonia. The rapid shallow respiration that caused the deficient action of the blood was believed to be due to an exaggeration of the Hering-Breuer reflex and experimental work had shown that this reflex could be abolished by adrenaline. Dr S. Davidson (Edinburgh) put in a strong plea for serum therapy. There was overwhelming indirect experimental evidence and also the direct evidence from the clinical results at the Rockefeller Institute. Much help with regard to prognosis could be given by the bacteriologist experienced in pneumococcal work. Sir James Barr spoke of the need for prophylactic measures and the use of common sense. Dr Hewat (Edinburgh) strongly recommended the use of alcohol. Dr Gardner-Medwin (St. Asaph) gave the results of his experience with intranasal injections of sodium nucleinate coupled with the oral administration of sodium bicarbonate and glucose. At whatever period the injection was made the crisis was precipitated in forty-eight hours. The cases on which the original work was done were severe cases with "heliotrope cyanosis" in the 1918-19 epidemic and the results were equally good in the pure pneumococcal pneumonias and in those following influenza.

Dr D. H. Billon (Montreal) gave a demonstration of the value of lipiodol in the investigation of intrathoracic disease illustrated by a series of most excellent lantern slides.

*Friday, July 22nd*

#### PATHOLOGY AND TREATMENT OF PERNICIOUS ANAEMIA

Professor Lovell Gulland (Edinburgh) opened the discussion with a short description of the general aspect of pernicious anaemia, giving as the principal criteria in diagnosis a high colour index, the presence of megalocytes, and leucopenia. The high colour index was due to the fact that red cell formation was megaloblastic rather than normoblastic. The disease was essentially a toxæmia, and the problem was—What is the toxin? It was generally regarded as haemolytic, but there was little real evidence of this in the sense of actual dissolution of corpuscles. The toxin probably inhibited the normoblastic function of the marrow, the development of neutrophils, and platelet formation, it produced sclerosis in the spinal cord, and indeed widespread changes in all the organs concerned with the elimination of poisons. No known organism could as yet be identified as the cause of the disease, the latest organism suggested was the *B. velvelli*. It had been surmised that with a low blood cholesterol the unsaturated fatty acids present in the blood in excess had a haemolytic action but in any case this could only be a secondary effect of some primary metabolic disturbance. Achylia also he considered to be a secondary factor. In contradistinction to the cryptogenetic form, there were several groups in which the cause was known, as, for example, biliary cirrhosis, some cases of sprue of syphilis and malaria, and of pregnancy. Turning to treatment, Professor Gulland said that, although from the point of view the treatment was unsatisfactory, it was possible to do a good deal, and 100 per cent should recover from a first attack. Rest, sunlight, and fresh air were important, and diet must be regulated by the alimentary condition. His experience of the high protein diet recommended by Minot and Murphy was limited; some patients had done well but others had not been able to take it and others had rebelled. Arsenic was our standby; it was best given as the hydrochloric solution by mouth in increasing doses and continuing with the largest dose compatible with freedom from arsenical symptoms until the colour index dropped below unity, it should then be stopped and iron given. Professor W. K. Hunter (Glasgow) said that discussion on the pathology of pernicious anaemia must centre round the two most notable features in its morbid

anatomy—namely, the evidence of increased destruction of red cells in liver and other organs and the changes in the bone marrow. He considered that there must be some definite haemolytic agent present and thought that it acted by stimulating phagocytosis of red cells. It was improbable that the megaloblastic marrow was entirely due to the increased haemolysis and in his view the megaloblastic change was the initial one produced by the toxin which determined the increased haemolysis. Dr G. P. Minot (Boston, U.S.A.) whose paper was read by the Honorary Secretary, described his results with a Liga protein liver diet. Statistics were given showing that of 125 cases treated practically all had recovered, the red cell count reaching to from 41 to 6 million in nearly all cases. The cases had been observed for periods of from four months up to three and a half years. The effect of the diet on the alteration in size and number and nature of the red cells was described. Recently Cohen had isolated a liver fraction precipitated by alcohol which apparently had all the properties of the whole liver in its effect on the marrow. Details as to various methods of giving the liver were described. Professor van den Bergh (L'recht) agreed with what the speaker had said but emphasized the importance of achlorhydria which was much more common in pernicious anaemia than in gastric catarrh. He had also noted that the red cells were elliptical in shape a condition characteristic of pernicious anaemia. Increased haemolysis with a breakdown of the Hb molecules was the basis of the disease and the bilirubin content of the serum was nearly always increased. Professor Knud Lærke (Copenhagen), after agreeing that pernicious anaemia was a symptom complex with many different causes, spoke of the extreme importance of infection in the upper alimentary tract in all cases of achylia or whatever origin the bacterial flora was abnormal. In his view the constitutional factor involved the blood rather than the stomach. While not denying the good results obtained by Minot's diet, he thought it was too early to use them to explain the pathogenesis of the disease. Experimentally he described showing the possibility of producing a megaloblastic anaemia by the injection of bacterial endotoxin. Dr A. F. Hurst (London) gave figures to show the very intimate association between achylia and peripheral radial achylia, with pernicious anaemia and subacute combined degeneration of the cord. Dealing with the bacteriology, Dr Knott had found that the normal duodenum was always sterile. In pernicious anaemia and subacute combined degeneration over 60 per cent were infected with *B. coli* or streptococci. He had never found *L. velvelli*. He regarded prophylaxis as of extreme importance and showing glossitis and tingling of the extremities should be carefully investigated and spic teeth removed and achlorhydria treated with hydrochloric acid. He had found a paper describing a method of preparing tablets so that it was very palatable and easily taken. Dr J. Schiff (U.S.A.) discussed the appearance of serum bilirubin—this was increased in pernicious anaemia but not in the secondary anaemias. Dr W. E. Coul (Wigan) described alterations in the polymorphonuclear neutrophil cell and suggested the probability that the intestinal flora was a product of abnormal off-putting from the haemoblastic. Dr S. Davidson (Edinburgh) emphasized the importance of the work done on *L. velvelli* infection; this organism was far more frequent in the stool of patients with pernicious anaemia than in normal people. Dr J. H. Sharpe (London) urged that the disease was due to infection by a spirochaete. Dr A. Blackall Morrison read a paper on coronary angina pectoris.

#### SECTION OF SURGERY

*Thursday, July 21st*

#### TREATMENT OF TOXIC COECITIS

Mr T. P. Duvigne (London), opening the discussion, said that in both true exophthalmic goitre and toxic adenoma there was a strain thrown upon the gland. When the gland was normal a true exophthalmic goitre resulted, but when the strain acted upon a physiologically hypertrophied gland which had failed to involute a secondary

exophthalmic goitre occurred. Many patients coming to him had had the disease for many years and had become worse in spite of medical treatment. Surgical treatment arrested the disease more quickly and certainly than medical measures. Early operation should be considered if the patient was not improving six months after the onset of the disease. Auricular fibrillation demanded operation. Usually he removed one lobe and the isthmus first, and a part of the second lobe later, it was extremely difficult to decide how much gland should be taken away. Professor G. R. Murray (Manchester) said that in some forms of toxic goitre only surgery could bring relief. It was more frequently required for secondary than for primary goitre, in which only about one-twelfth of the patients required an operation for relief as x-rays or radium were usually effective. Mr C. Thurstan Holland (Liverpool) made an eloquent appeal for x-ray treatment, which had no mortality attached to it. He thought x-rays should always be used in early cases and be given a short trial in the advanced ones. Professor R. E. Kelly (Liverpool) pointed out the advantages of intratracheal anaesthesia and preliminary iodine medication. Dr John Erson (Edinburgh) declared death to be a remote possibility in primary exophthalmic goitre. Operation, whilst it acted quickly in restoring normal function, raised the general death rate from the disease. He regarded it as necessary when there were signs of deterioration of the internal organs. A general policy of operation was wrong. Sir William de Courcey Wheeler (Dublin) pointed out the occurrence of eyes in the disease. Among 82 personal cases 90 per cent had had medical treatment and had passed into a chronic stage. He believed the only way to prevent relapse was a subtotal thyroidectomy. Iodine was very valuable, but might give a false sense of security. Mr John Morley (Manchester) said that only x-rays and surgery had any effect at all upon the disease. Owing to the use of Lugol's solution the operative mortality had been very greatly reduced of late years. He thought seven-eighths of the gland should be removed. X-rays failed to influence cardiac disturbances. Mr A. J. Wilton (London) stated that diffuse colloid goitre, if it persisted into middle life, was transformed into diffuse adenomatous goitre. This kind of gland rarely gave rise to thyrotoxic symptoms. There were two types of exophthalmic goitre—vascular and nervous. The latter was frequently unrelieved by operation. Medical treatment had a considerable mortality. X-rays were useless except for carcinoma. The use of Lugol's solution was good. Dr L. A. Rowden (Leeds) said that in an experience of 550 cases treated by x-rays he had come to regard this method of treatment as the best. It was often necessary to give such a dose that the skin was damaged. Dr F. N. G. Stair (Toronto) had known death to occur soon after x-ray treatment and had seen many failures. During 1926 he and two assistants had operated upon 253 patients for goitre. Only 27 were non-toxic. Two exophthalmic symptoms had sometimes been associated with adenoma. Mr Cecil Joll (London) had never seen exophthalmic symptoms in toxic adenoma, though he had had a very extensive experience. Much judgement was necessary to decide how much gland to remove. The mortality was less in operations for toxic adenoma than in exophthalmic goitre. Mr Dunhill replied that he did not operate in the early stages, and that he considered opinion was gradually crystallizing as to the place surgery should take in the treatment of the disease.

#### TREATMENT OF INFECTED WOUNDS

Sir Almoth E. Wright (London) demonstrated the principle of wound treatment. He gave an outline of his researches into the conditions which determined the persistence of infection in a wound, and showed how the flow of serum to the infected surface was the best method of destroying bacteria. He described the factors favouring the growth of the gas gangrene bacillus, and demonstrated the relative futility of the simple irrigation of wounds. He also explained how the addition of antiseptics to wound discharges lessened their antibacterial power. Hypertonic salt was a much better therapeutic agent.

Friday, July 22nd

#### CHRONIC APPENDICITIS

Mr Wilfred Trotter (London) classified chronic appendicitis under three heads. In one of these the disease was chronic from the beginning and gave rise to symptoms which were due to an associated mesenteric lymphadenitis, disturbances of motility or secretion at the ileo-caecal angle, or to general septic absorption. Cholecystitis was definitely related to appendicitis and was apt to occur in young persons, urinary infections were also seen. In children disturbances of growth, pustular skin eruptions, and some cardiac disorders were sometimes attributable to chronic appendicitis. He outlined his procedure in operating upon patients in whom the diagnosis was a little uncertain. Mr J. W. Dowden (Edinburgh) confined his remarks to methods of diagnosis. He described the conditions which simulate appendicitis, and how they could be distinguished. Mr Victor Bonney (London) emphasized the frequency with which chronic salpingitis or ovarian blood cysts gave rise to symptoms resembling chronic appendicitis. He advised a mid-line incision for operating upon women who were thought to suffer from appendicitis. Mr A. J. Wilton (London) doubted the existence of primary chronic appendicitis, changes seen in the appendices of such cases he regarded as evolutionary in character. Appendicular dysplasia was a real disease, but very rare. He did not remove the appendix as a routine when operating upon the upper abdomen. Mr H. N. Fletcher (Brighton) found in a follow-up of 82 cases of chronic appendicitis that operation failed to cure in about one-third. In the diagnosis he regarded the history of a previous acute attack as very important. Mr A. H. Burgess (Manchester) said he explored the whole abdomen in all cases of chronic appendicitis. He regarded tenderness in the right iliac fossa as an extremely valuable sign if it was proved to be greater than that caused by symmetrical pressure on the left side. Mr Andrew Fullerton (Belfast) urged that the specific gravity of the urine coming from each kidney should be estimated and compared in every doubtful case. By this means a renal origin of the pain could be excluded. Mr G. H. Colt (Aberdeen) relied upon gurgling in the right iliac fossa when pressure was made there as the most certain sign of chronic appendicitis. Mr H. Temple Muisell (Johannesburg) called attention to Rovsing's sign of pain in the appendicular region on pressure over the left iliac fossa, he believed it reliable. Professor D. P. D. Wilkie (Edinburgh) thought that perhaps there was a tendency to precipitate operating for pain in the right iliac fossa. He deprecated this and urged the education of the public so that they could be induced to undergo a complete investigation by modern methods before insisting upon operative exploration. He did not believe much in the simple x-ray diagnosis of chronic appendicitis. Mr Trotter, replying, said he regarded chronic appendicitis as often the initial stage in a long train of symptoms. He thought for this reason the effective treatment of the disease in childhood was important.

#### BURNS

Mr A. MacLennan (Glasgow) reviewed methods of treating burns, and gave his experiences. Mr Wilson (Edinburgh) gave an interesting account of the use of tannic acid in the treatment of burns and showed some remarkable lantern slides of the results of its use.

#### SECTION OF OBSTETRICS AND GYNAECOLOGY

Thursday, July 21st

#### HYGIENE OF MENSTRUATION IN ADOLESCENTS

Professor R. W. Johnson (Edinburgh), opening the discussion, said that the period of adolescence in the British race extended from about the age of 12 to 18, varying within limits in each individual. He described the anatomical, physiological, and psychological changes of puberty, and said that it was obvious that at such a critical period unhygienic methods of living might easily produce disastrous results affecting both body and mind. The reproductive organs during this phase of life called for a specially good supply of healthy blood and nerve energy.

and if these were diverted either to the muscular system or the intellectual centres the proper development and early functioning of the reproductive organs were liable to suffer. A natural mode of life must be aimed at including the avoidance of excess in any direction, physical or mental. But almost as much damage might be done both to the reproductive functions and to the nervous system by encouraging a girl to believe that she was the subject of a very special delicacy during the menstrual period. From time immemorial menstruation had been regarded as a function imbued with mystery and to some extent that idea still persisted. If they could dispel the lingering relics of such morbid tradition the next generation would suffer less from dysmenorrhoea. He advocated individual instruction of each girl as she reached puberty, so as to ensure in each individual the recognition of menstruation as a normal physiological function during which a moderate amount of wholesome exercise was actively beneficial. Dr J. H. P. Paton (St Andrews) questioned the wisdom of allowing girls to take part in active games during menstruation. His rule was to stop violent forms of exercise but to encourage walking and his results were very satisfactory. He estimated the occurrence of dysmenorrhoea among girls of a high standard of general health at about 9 per cent, the low incidence being due to good general condition. He referred to the question of regularity showing that intermittent amenorrhoea was comparatively common, due to the severe mental and physical strain of a school term. Dr Alice Sanderson Clow (Cheltenham) referred to the somewhat earlier onset of the catamenia in the children of well-to-do parents than in those of the poorer classes. They were not justified in regarding a case as one of primary amenorrhoea so long as growth in height and weight continued. She allowed girls to continue games such as tennis and hockey and to take warm baths. She had reduced the proportion of those suffering from dysmenorrhoea by these measures from 46.7 per cent to 10.8 per cent, and the majority of the latter were not permitted by their parents to take the exercise advised. Dr Vaughn Swyer (London) thought that the specific severs of childhood were largely responsible for the incidence of dysmenorrhoea. Dr G. I. Strachan (Cardiff) recounted his experiences in connection with a large mental institution. Professor Gibbon FitzGibbon (Dublin) said that the cases of dysmenorrhoea seen by the gynaecologist were mainly those of acquired dysmenorrhoea in girls aged 20 to 25. Professor McIlroy (London) thought that girls without occupation were the most frequent sufferers from dysmenorrhoea. The discussion was continued by Dr Catherine Chisholm (Manchester), Dr Mabel Ramsay (Plymouth), Dr Farquhar Murray (Newcastle), Dr Jeffries (Brighton), Professor Hendry (Glasgow), the President Dr Haultain (Edinburgh) and Dr Sutherland (Australia). It will, it is hoped, be published in full in an early issue.

Friday July 22nd

#### SHORT COMMUNICATIONS

The final meeting of this Section was devoted to a series of short communications. Dr T. A. E. Crer (Edinburgh) read a paper on the effects upon the sex ratio of conception, early and late in relation to the oestrous cycle of the rat. His results appeared to show that the time of service in the oestrous cycle was of no importance in determining the sex ratio. The paper was discussed by Dr James Young (Edinburgh) and the President. Dr Fletcher Shaw (Manchester) discussed uterine fibroids after the menopause and urged that in view of the dangerous changes which might be undergone by fibroids their earlier removal was desirable. The paper was discussed by Dr Bethel Solomons (Dublin), Professor McIlroy (London), Professor FitzGibbon (Dublin), Dr Fordyce (Edinburgh), Dr James Young (Edinburgh) and the President. There was a general agreement among most of the speakers with the conclusions reached by Dr Fletcher Shaw. Dr Daniel Douglass (Manchester) reviewed the clinical features of ectopic pregnancy, based upon a hundred cases which had been under his care. Dr Leith Murray (Liverpool), Dr Bethel Solomons (Dublin), Dr Farquhar Murray (Newcastle), Dr Forsyth (Edinburgh),

Professor R. J. Johnstone (Belfast), and the President raised interesting points in connexion with the paper. Dr Bethel Solomons described his experiences of lower segment Caesarean section and the indications which in his view called for its performance. Dr FitzGibbon, Professor McIlraith (Toronto), Professor Hendry (Glasgow), and the President took part in the subsequent discussion. Dr Douglas Miller (Edinburgh) reviewed the clinical results in 83 cases of failed forceps delivery which had occurred in 500 emergency admissions to hospital. Unfortunately time did not permit of an adequate discussion of this most important paper.

#### SECTION OF THERAPEUTICS AND PHARMACOLOGY

Thursday July 21st

##### THERAPEUTIC USE OF CALCIUM SALTS

Professor F. R. Fraser (London) opened this discussion. He said that the function of calcium in the living organism was imperfectly understood, but it was known that it was essential in the clotting of blood. It appeared also to be necessary for the proper contraction of heart muscle, and it played an important part in the balance of ions in the tissues and body fluids. Professor Fraser dealt with the indications for calcium therapy, and observed that the effects of administration by the mouth were inconsistent and at best only produced a moderate rise in the level of the calcium in the serum in healthy subjects. Intravenous injections of calcium chloride could be utilized to raise the serum calcium promptly; the effect was transitory, but the method was useful in controlling the severer manifestations of tetany—namely, the convulsions and laryngismus. Indirect methods of influencing the calcium content of the body were perhaps more important than the direct administration of its salts. Dr L. G. Parsons (Birmingham) restricted his remarks to the treatment of children with special reference to tetany and bone calcification. He seldom gave calcium by the mouth, since he thought the child obtained sufficient from the food. Dr C. P. Stewart (Edinburgh) dealt with calcium absorption, in that process acidity in the intestine was an important factor. He said that careful distinction must be made between absorption and retention; he had shown experimentally that the parathyroid hormone had no effect in either process. Dr G. H. Pereira (Edinburgh) had found that the calcium content of the serum was very constant, symptoms occurring only when it was greatly reduced. Therapeutic value was disappointing and it was only when some controlling mechanism in the body failed that the amount in the body diminished. In pregnancy and lactation the content was low owing to the supply in the food being insufficient for both mother and child. Professor L. Blum (Strasbourg) exhibited charts showing that calcium chloride diminished oedema by promoting diuresis. He also referred to the employment of calcium salts in pleurisy. Dr F. C. Lind (London), Dr N. C. Burges (London), Dr C. G. Lambie (Edinburgh) and the President continued the discussion.

Friday July 22nd

##### OVARIAN EXTRACTS

Professor W. E. Dixon opening a discussion on the action and uses of ovarian extract said there was no doubt that the ovary was an organ of internal secretion. If an ovary was transplanted into an animal before puberty it did not grow or function and therefore, there must be in the body something else necessary for its growth and function. Clinical results with ovarian extracts had been disappointing possibly owing to their having been administered in a haphazard and unscientific manner. Professor Dixon considered in detail the three main instances contained in extracts of ovarian glands—namely (1) oestrogen which when injected into animals produced oestrogenic effects of the sexual organs; (2) lutein which had the effect of inhibiting the oestrogen period and (3) pituitary. He emphasized the fact of the close relation between the pituitary gland and the ovary. Miss Katherine Corbridge (London) gave an account of the results of injection of ovarian extracts in rats and mice after removal of the ovaries, and described her method of standardizing the

doses of ovarian preparations Dr A S Pules (London) said that he had shown experimentally that the presence of the corpus luteum in the mouse was essential for the continuance of pregnancy, an active corpus luteum extract was necessary in ovarian extract therapy, but so far only in oestrous hormone was available for use Dr W R Addis (Manchester) related the results of investigations with extract of ovary without corpus luteum to produce labour, in fifty cases There had been complete absence of consciousness of uterine contractions by the patient in the first stage of labour, and no pain until its end, thus approximating the condition in lower animals and the savage races Dr W F T Haultain (Edinburgh) described the effect of giving ovarian extracts after operations in which both ovaries had been removed Dr Kennedy, Dr Campbell, and Professor Greeno contributed to the discussion

#### THE ACTION OF DIGITALIS

Professor D Murray Lyon (Edinburgh) read a paper on the action of digitalis, illustrated with lantern slides

### SECTION OF DISEASES OF CHILDREN

Thursday, July 21st

#### ACUTE INTESTINAL OBSTRUCTION IN INFANCY AND CHILDHOOD

Mr A MacLennan (Glasgow), who opened this discussion, dealt first with obstruction due to congenital anomalies, citing in turn duodenal stenosis, jejunal and ileal atresias, colic obstructions, exomphalos, Meckel's diverticulum, and strangulated hernia He then considered acquired causes and protested against the classifying of intussusception among the obstructions, on the ground that this led to delay in operating Symptoms which had a mechanical explanation and those which were due to interference with function were discussed He emphasized the desirability of wishing out the stomach early in the anaesthetic period, and of avoiding handling He did not hesitate to perform enterotomy, and was not altogether opposed to chloroform as an anesthetic in these cases Mr Brunning-Wood (London) indicated the relative diagnostic value of the different symptoms and signs of obstruction, and referred at some length to internal hernia and volvulus of the small intestine In the treatment of intussusception he recommended Farr's method of injecting air into the large gut as an adjunct to operation Miss G M A Heifield (Edinburgh) reported 160 personal cases, 116 of acute intussusception (24 deaths), 16 of obstruction due to abdominal tuberculosis (6 deaths), 22 of irreducible and strangulated hernia (no deaths), and 6 of post-operative obstruction in acute appendicitis (1 death) She mentioned the importance of combating dehydration before operation As an anesthetic she preferred open ether combined with local infiltration with novocain She had also used spinal anaesthesia with success

Mr F C Pybus (Newcastle-on-Tyne) referred to the variation in the symptomatology according to the nature of the obstruction, and to the difficulties in diagnosis presented by ketonuria and Henoch's purpura He disliked chloroform as an anesthetic

Mr N M Dott (Edinburgh) suggested that children suffering from acute intestinal obstruction tolerated operation remarkably well, and that therefore it was doubtful whether the loss in debility and accurate technique did not nullify any gain due to speed in operating He thought that resection was possibly the best treatment in certain cases, in which the bowel, though reducible and viable, was severely bruised in the process of reduction Dr H C Cameron (London) mentioned the need for early diagnosis when there were grave symptoms of intestinal obstruction in a newborn infant With regard to acute intussusception, he called attention to the contrast in practice prevailing in Scandinavia, where in 80 per cent of cases taxis through the abdominal wall without laparotomy was successful He referred also to the differential diagnosis of intussusception from colitis and Henoch's purpura and to the value of blood transfusion Dr Lapage (Manchester) dealt with

points in diagnosis and pleaded for the avoidance of purgation Dr Margaret Tod (Edinburgh) emphasized the practical difficulties of distinguishing between enteritis and intussusception She was convinced of the value of transfusion

Friday, July 22nd

#### THERAPEUTIC MODIFICATION OF INFANT DIET

Dr H C Cameron (London), opening a discussion on the therapeutic modification of the diet in infancy, deplored the neglect of pediatrics in medical education and the dearth of professorial chairs The therapeutic modifications of the diet to which he directed particular attention were (1) high caloric feeding in post-infective dystrophy, (2) thickened feeding in the vomiting of aerophagy, nervous vomiting, and hypertrophic pyloric stenosis, (3) feeding with a high percentage of casein in fermentative diarrhoea Dr Dingwall Fildyce (Liverpool) thought that chemical tests of breast milk were of comparatively little practical value, but that occasionally bacteriological examination proved of the utmost importance In artificial feeding each case must be taken on its merits Dietetic modifications might produce their effects by influencing endocrine, particularly thyroid, activity Dr G B Fleming (Glasgow) thought that underfeeding was an extremely common cause of malnutrition, and discussed the food requirements of normal and malnourished infants Observations on basal metabolism were quoted Dr Lewis Thatcher (Edinburgh) dealt with the use of acidified milk, and spoke highly of the value of lactic acid milk, illustrating his remarks by charts Dr L G Parsons (Birmingham) gave his experience of milk acidified by the *Streptococcus lactis* He suggested that lactic acid was synthesized in the liver to carbohydrate Dr C W Vining (Leeds) mentioned the common tendency to underfeed the artificially fed infant, and commented on the confusion which resulted from slack methods of measuring quantities of solid and liquid food-stuffs He referred to the use of banana pulp Dr Catherine Clusholm (Manchester) discussed the teaching of this subject and the utilization for teaching purposes of the clinical material in Poor Law and similar institutions Dr Mary Lowenfeld (London) mentioned observations on the quantity and composition of the feeds taken by normal breast-fed infants, and with special reference to factors modifying the fat content Dr Dorothy Potter (Edinburgh) referred to methods of feeding in use in the Toronto Children's Hospital Dr Helen Mackay (London) commented on the great variation in bulk of different food-stuffs Dr C McNeil (Edinburgh) stressed the importance of the clinical observation of the individual child in relation to its feeding

### SECTIONS OF NEUROLOGY AND MENTAL DISEASES.

Thursday, July 21st

#### EPIDEMIC ENCEPHALITIS

Under the chairmanship of Professor Edwin Bramwell the second day's proceedings were devoted to a discussion on epidemic encephalitis, opened by Dr Ivy McKenzie (Glasgow), who dealt with the epidemiology of the disease and described its history Passing to the pathological anatomy, Dr McKenzie said that he had found that in the acute and early stages the lesions were diffuse, and tended to be more pronounced in the basal nuclei and in the mid brain In Parkinsonian cases the most pronounced lesions were in the substantia nigra It was clear that the possible toxin responsible for the disease showed a predilection for the grey matter on the afferent side of the proprioceptive system Dr McKenzie concluded by giving a short history of the disease in Glasgow Dr J G Greenfield (London) stated that the virus of epidemic encephalitis had not been identified yet, and it was still uncertain whether the disease had ever been transmitted to animals Some workers claimed that the etiological agent was identical with that of herpes febrilis, differing from it only in possessing a greater affinity for the nervous system In the early stages the cerebro spinal fluid might be quite normal or might contain a slight excess of glucose, which was of doubtful significance Usually in the first few weeks of the disease, however, there was a lymphocytosis of 10 to 100 or even more cells per cubic millimetre Dr Greenfield's

paper was illustrated with some admirable photomicrographic slides of sections of the brain showing different phases of the disease. Dr C Riddoch (London) considered the chronic forms of the disease, and maintained that encephalitis lethargica was a chronic malady, comparable in its course with neurosyphilis and disseminated sclerosis. An important group of cases was that in which the disease appeared to be chronic from the beginning. Dr Riddoch discussed the milder forms of Parkinsonism the most different kinds of involuntary movements, spastic paralysis, and muscular atrophies. He also described the various forms of respiratory disorders, and concluded by referring to the interesting endocrine involvements—adiposity, diabetes insipidus, and glycosuria—which sometimes followed the disease. Dr R MacNish Marshall (Glasgow) dealt mainly with the mental aspects of the disease, including (1) the clinical importance of the course (2) the incidence of the characteristic sequels (3) the mental state of the restless, naughty child, (4) the clinical affinities of the Parkinsonian syndrome. Professor G Guillian (Paris) described some cases, complaining of symptoms that at first appeared to be those of myasthenia gravis. Subsequent investigation showed the cases to be examples of post-encephalitic disorders, which illustrated the importance of fully investigating the physical signs in all cases of apparent myasthenia. Dr E Mapother (London) described cases that at first had appeared to be neurases. The intensity of the mental symptoms seemed to bear no relation to the degree of the physical disabilities. Dr B Sachs (New York) said that the lethargy of epidemic encephalitis differed from all other forms of lethargy, and considered that "central basilar encephalitis" was a better term to apply to the disease than encephalitis lethargica. Dr W A Potts (Birmingham) regarded the routine treatment of any focal sepsis, whether nasal, dental or intestinal, as most valuable even in chronic forms of the disease. He had seen good results following the use of autogenous vaccines made from organisms cultivated from the nose and throat. Professor R Cruchet (Bordeaux) spoke of the important sign of defective muscular relaxation in the diagnosis of post-encephalitic states. He also showed a myogram illustrating the increase in the relaxation-time in Parkinsonian cases, together with others demonstrating the greater degree of relaxation time following the injection of scopalamine. Professor K A Petren (Sweden) had found Guillian's "blinking reflex" a valuable diagnostic sign. In his experience no case had ever developed Parkinsonism at a longer interval than four years from the onset of the disease. Dr V D Ryle (New South Wales) gave a cinematographic demonstration of cases of post-encephalitic Parkinsonism illustrating the benefit following sympathetic ramisection. Dr J H Wolfsohn (San Francisco) had seen benefit in many cases follow the use of a polyvalent autogenous vaccine (from mixed nasal and intestinal cultures) applied immediately following the acute stage of the disease. Dr T A Ross (Penshurst) emphasized the importance of an adequate history in diagnosing neurosyphilis from post-encephalitic states. Dr Poston (Manchester) dealt with the relation of oculomotor disabilities to vestibular function, and Dr P C Cloake (Birmingham) commented upon certain mental aspects of the disease.

## SECTION OF LARYNGOLOGY AND OTOTOLOGY

Thursday, July 21st

### OTO-CLEOSIS

Dr J C FRASER (Edinburgh), in some opening remarks as chairman, pleaded for international investigation into oto-cleosis and also for term work between the otologist, the physician, the neurologist, the biochemist, and the endocrinologist. Mr G J Jenkins (London) in opening the discussion on otosclerosis is said that this term should include a variety of syndromes, and not merely the middle-ear deafness type of otosclerosis. Osteitis deformans deafness might simulate that of otosclerosis in all types, but in some cases the deafness might be due to the grafting on of true otosclerosis. Osteogenesis imperfecta did not itself cause deafness, but it favoured the implantation of true otosclerosis. The clinical peculiarities in the Eustachian tube, middle ear, tympanic membrane and external audi-

tory memans, which were commonly found in otosclerosis, were probably anatomical variations or a local defect, and were not due to otosclerosis, the peculiarities probably favoured the onset of otosclerosis. The symptoms and signs of otosclerosis were not due to primary disease in the labyrinth, but were secondary to a capsular bone disease extending to and involving the central elements. Professor F R Nager (Zurich) said that in 800 cases of deafness examined in private 200 were cases of otosclerosis. The sex incidence was 18 females to 1 male. Most cases started between the ages of 21 and 25, and after the fiftieth year very few cases were to be found. Of the patients, 58 per cent had a definite family history but heredity in otosclerosis was not uniform. The progressive character of the deafness might be slow, with in some cases, long stationary periods but very often it was marked by severe attacks of tinnitus. A diagnosis could only be patients 58 per cent had a definite family history but he did not hesitate to diagnose otosclerosis even when the membrane was thickened or not quite normal. In 71 per cent of his cases the drums were normal, and 20 per cent showed a redness of the region of the promontory. Professor Nager illustrated his paper with beautiful slides in colour photography. The discussion was continued by Dr Dan McKenzie (London) who pleaded that any method for the treatment of otosclerosis should be given a definite trial such as re-education and constitutional method. Dr Guthrie (Edinburgh) and Dr Scott Stevenson (London) spoke on the re-education of the deaf by method such as the Zund Buguet. Sir James Dundas-Grant (London) Dr O Miller (London), Sir William Milligan (Manchester) Dr Musgrave Woodman (Birmingham), Dr Wright (Bristol), and Dr Cathcart (London) also spoke and Dr William Hill (London) gave an account of the treatment of otosclerosis by radium, which, however, he did not find very effective.

## SECTION OF PREVENTIVE MEDICINE

Thursday, July 21st

### THE STATE AND THE FOOD SUPPLY

Dr HAPPIFFY CHICK presided over the Section and briefly introduced Professor Mellanby who read the opening paper on the question of the duties of the State in relation to the nation's food supply regarding research in the maintenance of food supplies and cooking facilities. He emphasized the importance of the diet factor in public health and the bewildering rapidity with which new knowledge on the subject was being gathered. He was convinced that the State had important duties to perform in connexion with both research and education and suggested the establishment of a new board of nutrition with powers to carry out these functions. Dr Eustace Hill (Durham) supported the proposal to form a board of nutrition. He pointed out the practical difficulties in the way of obtaining opportunities for the nutrition of parents and advocated better teaching or hygiene in the elementary school. Profiteering in food was a national question. It was an unfortunate that retailers preferred large profit and a small turnover to a large turnover with small profits. The consumer never received the benefit of a glut of either fruit or vegetable and a better system of distribution was required which would eliminate the middleman. Dr Kinloch (Aberdeen) protested against the attack on oatmeal which was a food that required to be balanced by vitamin giving elements in food. With this addition it was a valuable form of diet. He further distrusted the suggestion for communal cooking. It would lead to interference with family life. It was never done by the State on these lines. He would prefer the establishment of communal laundries which would relieve the mother of the drudgery of the wash and the father of the trouble to cook better meals for her family. Dr Gifford Leighton (Scottish Board of Health) agreed that the State had fundamental duties in connexion with the control of raw material. It had already fulfilled many of these duties through legislation regulating the milk supply, the distribution of preservatives in food and regulation governing the handling of meat. He believed that more progress had been made in purifying the milk supply in this country

years than in the previous fifty Sir George Newman (Ministry of Health) briefly described the action which the State now took in regard to nutrition which lay at the foundation of national health Dr Macgregor (Glasgow) said that owing to prolonged unemployment and other causes many of the people had only enough money to buy the bare necessities of life, yet vital statistics showed a marked improvement in health conditions The only conclusion was that old nutritional standards based on calories were fallacious

#### PULMONARY ASBESTOSIS

Dr Cooke (Wigan) showed a number of slides illustrating the microscopic structure of asbestos the nature of asbestos dust, and the histological appearances of the lung in a fatal case Sir Thomas Oliver (Newcastle) described the clinical features of a series of cases and pointed out the importance of the subject in view of the greatly extended use of asbestos and the increase in the number of persons engaged in its manufacture Professor Stuart McDonald (Newcastle) showed a number of slides illustrating the pathological changes in the lungs which resulted from asbestosis and especially the very remarkable foreign bodies which developed in the tissues There was some doubt as to the nature of these bodies and it had been suggested that they might be animal or vegetable in origin, but he inclined to the view that they were products of the hydrolysis of asbestos

### SECTION OF PHYSIOLOGY AND BIOCHEMISTRY

Friday, July 22nd

#### CHEMICAL CHANGES ACCOMPANYING MUSCULAR ACTIVITY

The second morning of this Section was devoted to a discussion of the chemical changes accompanying muscular activity, after which various short papers were read Professor T H Milroy (Belfast) opened the discussion by reviewing earlier work, and said that Embden now regarded "lactacidogen" as a monophosphoric ester The presence of phosphoric acid ester was essential for lactic acid production, but esterification and lactic acid production occurred simultaneously and in equimolecular proportions Esterification in the presence of fluoride which prevented lactic acid production, was accompanied by increase in acidity, which had been shown by Meyerhof to be due to the higher dissociation constant of the ester acid than the normal Muscular activity was shown to be accompanied by changes in permeability The free phosphate union liberated during activity was retained and was of importance during the recovery period Professor O Meyerhof (Berlin), dealing with the energetics of muscular contraction, said that besides the formation of lactic acid the splitting off of a new compound containing creatine and phosphite (discovered by Eggleton and Fiske) played an important part in the supply of energy producing a third of the whole heat of contraction Professor G Embden (Frankfort-on-Main) considered the production of ammonia as an accompaniment of muscular contraction He reviewed a large number of experiments and showed that the amount of ammonia varied under different conditions The nature of the precursor of ammonia was discussed Sir Gwlad Hopkins (Cambridge) referred to observations upon muscles made non-irritable by a prolonged stay in oxygen and restored by solutions of certain electrolytes After this discussion Professor J Mellanby (London) read a paper on the function of bile in which he showed that bile was the normal stimulus for the secretion of pancreatic secretion The question of fat absorption from the small intestine was also dealt with Professor J Traut (Montreal), in a paper on the natural arrest of haemorrhage from wounds said that this was due to agglutination of thrombocytes Coagulation of the plasma on contact with connective tissue aided in the process, but this factor was absent if the vessel had been denuded of its adventitia before puncture Dr C Harrington (London) read a paper on the constitution of thyroxine, the isolation and synthesis of the substance were described Professor R J McDowell (London) read a paper on physiological considerations in high blood pressure He discussed the various factors

which brought about the increased vasomotor action Dr H Whitridge Davies and Professor B A McSwiney (Leeds) read a paper on the circulation rate Experiments were described which showed that measurements made by the ethyl iodide method did not agree with those obtained otherwise

#### HAEMOLYSIS

In the afternoon a discussion on haemolysis was opened by Dr Eric Ponder (Edinburgh) who, after referring to the recent proofs of the lathane-like structure of the mammalian erythrocyte and of the presence of protein as a principal component of its envelope gave a short account of the kinetics of the action of the simple haemolysins such as soap, bile salts, and soaps He next emphasized the fact that in many of the more complex systems it was important that the components should be mixed in a particular order For example the addition of serum to a cell suspension before the addition of sodium tartrate inhibited haemolysis but adding the same amount of serum to the mixture of tartrate and cells resulted in great acceleration In the first case a mere substrate was formed, but in the second in which the lysin was adsorbed to the cell before the addition of the serum the combination of lysin and serum protein appeared to produce a very and very haemolytic substance He cited similar occurrences in the sensitization of cells with brilliant green and in the case of lysis by colloidal silicic acid and complement He concluded by indicating the bearing of these findings on the problem of the action of complement and antibody Professor J Mellanby (London) discussed the action of enzymes on the red blood cells Dr R Brinkman (Groningen) dealt with the reversibility of haemolysis Sir E Sherrin-Schäfer questioned the reversal changes and Dr Eric Ponder replied that in his opinion there was no fundamental difference between the kinetics of the complement and the antibody systems and of simple acid and simple lysins

### SECTIONS OF PATHOLOGY AND BACTERIOLOGY AND COMPARATIVE MEDICINE

Friday, July 22nd

#### PROBLEMS OF COMPARATIVE MEDICINE

The chairman Dr O Charnock Bradley expressed his gratification at the inception of this new Section and remarked on the already deep debt that veterinary education in Edinburgh owed to human medicine in that city The discussion on problems and aspects of comparative medicine was opened by Professor B Burton (Cambridge) who considered the various general aspects of the subject and the advantages of co-operation between the medical and veterinary professions Dr Andrew Balfour (London) directed attention to the essential unity of human and veterinary medicine and the methods by which this unity might be realized In tropical medicine this was very apparent more so than in many other branches He detailed many examples of advances in human tropical medicine which depended on animal experimentation and research Mr W H Andrews (Ministry of Agriculture) discussed the problems of filterable viruses, and drew attention to the advantages enjoyed by the veterinary pathologist in being able to select the actual species of animal suffering from the disease Professor Lyrain Sturges considered that the main problem lay in the application of experimental method to medicine and showed how animal experimentation had thrown light on many obscure human conditions Professor Browning pointed out the need for considering the peculiarities of the animal species the diseases of which were being investigated

Mr James McAllan (Aberdeen) dealt with the question of milk and meat inspection in regard to public health and believed that this should be in the hands of a veterinary officer under the administrative direction of a medical officer of health Professor Macleod discussed the work of his department in connection with the Edinburgh Zoological Gardens and the bearing of this work on comparative medicine Dr R A O'Brien (Belfast) expressed his belief in the benefits resulting from the co-operation between veterinary and medical workers and discussed the translation of the results of their work

into field experiments. Dr Nasmyth thought that comparative medicine could help to explain the periodic outbreaks of epidemics and the disappearance of certain types of disease from certain localities, and pleaded for the incorporation of the veterinary colleges in the universities and the extension of veterinary research.

Dr F. A. E. Crew considered it futile to talk about co-operation between professions, contact being essentially individual. The study of mankind was by no means only man, and those in power should take advantage of the already existing co-operation and extend it. One of the great problems of the future was the evolution of a disease-resisting stock. Lieut Colonel Greig discussed the importance of joint work by the medical and the veterinary professions and quoted examples from his own experiences in India. Dr T. W. M. Cameron stated that, while there was unanimity as to the value of co-operation between the medical and veterinary professions, no one had attempted to formulate a definition of "comparative medicine." It was neither "veterinary medicine" or "diseases common to man and animals," but the comparison of all the sciences which comprised medicine as applied to the whole of the animal kingdom. Viewed in this light comparative medicine was really medicine, and both human and veterinary medicine were sister sciences both subsidiary to a wider science, which had as its aim the elucidation of the laws and principles governing the cause, spread, and relief of disease.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL

#### INJECTIONS OF ACRIFLAVINE FOR TUBERCULOSIS

The use of subcutaneous injections of acriflavine in tuberculosis was suggested by G. H. Johnson<sup>1</sup> and unfavourably reported on by R. J. Gittins<sup>2</sup>, yet, in view of the bankruptcy of medicine in the face of this disease, every promising drug deserves an extensive trial. In recording the following cases I am actuated by the belief that all statistics are of value, for it is only by weighing the accumulated evidence of numerous observers that the effects of acriflavine in tuberculosis may be appraised.

The injection given in all cases consisted of 1 c.c.m. of 1 in 1,000 acriflavine in saline, it was given twice a week. All the patients were treated in the open air on the usual lunics.

F. W. male aged 5. Tuberculosis of dorsal spine. Ten weeks acriflavine treatment. General condition seemed rather worse.

T. S. female aged 7. Tuberculosis of dorsal spine with sinuses and amyloid disease. Slow improvement for past year. Six weeks acriflavine treatment. No apparent effect.

C. D. female aged 13. Tuberculosis of cervical spine with sinuses. Slow improvement during past eighteen months. Six weeks acriflavine treatment. No apparent effect.

R. M. male aged 10. Advanced phthisis. Ectetic temperature. Four weeks acriflavine treatment. No apparent effect. Temperature unaffected.

J. B. male aged 15. Advanced phthisis. Three weeks acriflavine treatment. Patient died.

W. M. male aged 6. Chronic tuberculous peritonitis. Ten weeks acriflavine treatment. No apparent effect.

W. B. male aged 10. Active tuberculous peritonitis. Three weeks acriflavine treatment. No apparent effect.

X. J. male aged 6. Tuberculosis of right hip with sinuses. Eleven weeks treatment. No apparent effect.

W. W. male aged 13. Advanced tuberculous disease of sacro-iliac joint and of iliac bone. Multiple sinuses. One month's acriflavine treatment. No improvement.

I am unable to convince myself that acriflavine has any effect on the course of the disease, those cases that were improving continued to progress, but those in whom the disease was active continued to go downhill.

I wish to thank Lieut Colonel P. MacDonald M.D. O.B.E., the medical superintendent of Alder Hey Hospital for permitting me to publish these cases.

READ AIDIN, M.D.  
Alder Hey Children's Hospital, Liverpool.

<sup>2</sup> Gittins R. J. Ibid. May 7th 1927.

## A PILLION RIDING ACCIDENT

The following rather peculiar injury has been brought to my notice three times in the last two months, and as it is a direct result of pillion riding—a pastime which although strongly condemned as dangerous, is without doubt becoming increasingly popular—I think it worthy of mention.

The patients were in all cases, young men who had been pillion riding astride. It seems from this that the majority of those injured will be of the male sex, for the pillion riding flapper usually elects to ride side-saddle.

The pillion rider, in order to obtain a more comfortable seat and also rest for his dangling feet, places his toes on the strand for the back wheel or any other convenient metal strut. A slight depression is encountered and the bump given to the back wheel moves one of his feet on its temporary rest and the heel, turning inwards comes into contact with the moving spokes of the back wheel and one of these causes the injury. The spoke catches the top of the heel of the rider's shoe and either rips off the shoe and tears the sock only, or, getting a deeper hold, tears down the whole heel flap as well. The heel flap usually ripped down in one piece, skin and subcutaneous tissue going together, and the lower end of the tendo Achillis and the posterior and inferior surface of the os calcis are exposed to a greater or less extent. The flap is attached at its lower end and retains a sufficient blood supply from the recurrent branches of the plantar arteries.

The wound, being made by a dirty spoke, requires early and thorough cleansing—irrigation with an antiseptic such as 2 per cent. acriflavine in normal saline—and should be loosely sutured. Healing is a little delayed on account of the nature of the injury and the part affected but in my cases was uneventful.

It appears as if special foot rests or wheel guards were required on all motor cycles which are going to be used for this form of recreation.

DOUGLAS I. CUPRIE, F.P.C.S.  
Surgeon, West Denbighshire Hospital, Colwyn Bay.

## MEASLES SIMULATING SCARLET FEVER

The following case is interesting and instructive in many ways.

I was recently called at midnight to a boy aged 2 years and 4 months. His mother said he had been out of sorts for a day or so and had been rather restless and feverish. He had a short dry cough and the general symptoms of a cold in the head such as running nose, sneezing, watery eyes, pains in the head and ears etc. That day he gave more definite symptoms of illness, such as sore throat and vomiting and when I saw him he had vomited again. His throat was very red and inflamed on both sides and on the posterior wall and although his bowels had recently moved he had a tongue having thick white fur with red papillae projecting through it—in fact what was almost certainly a strawberry tongue. The temperature was 103 and the pulse 140.

In both popliteal spaces there were several small bright red spots which were not raised and were distinct from each other. There were no other spots on the legs but on both elbows similar spots were found. There were no spots on the chest or abdomen and back or front and except for one or two on either cheek the face and head were also entirely clear.

I saw the child again at 11 o'clock the next morning when there was a fairly profuse rash on chest and abdomen and also on the limbs while the throat was still sore. The temperature was 101° and the pulse 130. After consideration I decided to regard the case as scarlet fever although I told the mother that I was not wholly satisfied and would not be very surprised if he did turn out to be measles as although the symptoms of scarlet fever were most prominent, the fact of the running nose and cough and short cough suggested measles to a certain extent. Accordingly the child was sent into the observation ward of the fever hospital and in a day's time I learned that the illness had turned out to be measles, not scarlet fever.

The rash appeared between the second and third days as is usual in scarlet fever and showed the very common bright red puncta. It also was specially evident at the bend of the elbow and elbow where it was somewhat inclined to be petechial, suggesting Paltauf's sign. The prodromal measles rash was less typical. The pulse was typical of scarlet fever, being 120 to 140 at 11 and then 130 while the temperature 103° and 101° was rather high for measles. The tongue had a very evident strawberry appearance but of course this occasionally to be found in measles and too much reliance is not to be placed upon it. The throat and mouth presented the appearance of a mild ordinary type of scarlet fever and although I looked for them most carefully no Koplik's spots were present. Only the cardinal symptom were really in favour of measles and they were rather overweighed by the other signs.

GLASGOW

JOHN WILSON, M.B., Ch.B. Glasgow

## Rebicus.

### COMPARATIVE PHYSIOLOGY OF THE HEART

THE book Professor A. J. CLARK has contributed to the new Cambridge series of volumes on comparative physiology is well worth reading and thinking over, if only for the reason that it is good at times to stand back from the mass of detail daily accumulating in the scientific journals and try to see the main outlines of our knowledge as they are being written by many hands. It is entitled *Comparative Physiology of the Heart*,<sup>1</sup> and the first impression it produces is that very little is really known about the working of the heart in the animal kingdom, here and there general conceptions of one or other aspect are emerging, but for the present we must remain content with the consideration of a number of isolated problems. Thus Professor Clark gives us a series of chapters, like short stories, on the transmission of the excitatory process, the nervous control of the heart, the work of the heart in relation to body weight, the influence of temperature and the influence of chemical environment on the heart's activity—each set of facts apparently distinct. Yet, in these and other chapters, we get an inkling of how in a multitude of widely different animals the heart, by variations in structure and mechanism, maintains an efficient circulation. Thus we learn of the simple tubular hearts of the lower invertebrates along which infrequent peristaltic waves slowly pass, and of the four-chambered heart of the canary, which contracts at the rate of 1,000 a minute. Again, we think of the hare and the rabbit with new interest when they are presented as extremely good examples of the contrast between the circulations of the athletic and non-athletic animals. The hare has a heart three times the size of that of a rabbit of the same bulk, and at rest the hare's pulse rate is only one-third that of the rabbit. The slow pulse of the hare is, however, due to vagal control, and when this control is removed the heart rates are similar. Simple abolition of vagal control, therefore, enables the hare to increase its rate of circulation fourfold, whereas the rabbit by this means can only produce an increase of 1.6-fold. The athletic animals as a class have large hearts, slow pulses, and a low oxygen utilization coefficient when it rests. This is an arrangement which permits a maximum increase in oxygen supply to the tissues during violent exertion.

In a short chapter on the properties of heart muscle Professor Clark shows us something of the relations between cardiac and other forms of muscle. The simplest forms of cardiac muscle—for example, the cells of the sinus venosus of the frog—resemble plain muscle closely in their general form, but they are striated and the cells are connected by thin strands. In the frog's ventricle the cells are shorter and thicker, the striations clearer, and the connexions between the cells thicker. In the mammalian ventricle these changes are carried a stage further. Skeletal muscle appears to be a further development from plain muscle, in that numbers of cells have fused completely to form fibres, and these fibres have no automaticity and are separated so completely that excitation is not conducted from fibre to fibre. Skeletal muscle is specialized to perform accurate rapid movements completely under the control of the nervous system, cardiac muscle is specialized so that a contraction, once initiated, spreads throughout the whole muscle. In skeletal muscle, since the refractory period is far shorter than the time required for the development of maximum tension, tetanus can easily be produced. In vertebrate cardiac muscle the absolute refractory period is considerably longer than the time required to produce maximum tension, and hence it is impossible to produce tetanus. The long refractory period of heart muscle, the author remarks, is a very obvious safeguard for an organ upon the continuous rhythmic activity of which the life of the individual depends.

These are examples of but a few of the many interesting things dealt with in this small volume, it is necessarily

incomplete, it is too short, but it is a good start. We echo Professor Clark's hope that it may stimulate research workers to provide more extensive and accurate information in this field of comparative physiology.

### INFECTIONS OF THE HAND

It has been said that there is nothing new under the sun, and even this remark has lost its novelty. Mr. LIONEL FIFIELD's book on *Infections of the Hand*<sup>2</sup> will herald no epochal discovery, but is, none the less, a thoroughly sound, workmanlike book, possessing no little originality and constituting an important contribution to a subject of unquestionable importance. If all house-surgeons, instead of thrusting to open the abdomen, would only make themselves masters of the principles laid down here, the advantage to many individuals in lessening of suffering, and the gain in money to the community at large, would be enormous. There is probably no branch of surgery which is on the average worse treated than infections of the fingers and hand. The public itself is no little to blame in this, as it habitually neglects injuries, often trivial enough at the outset, but essentially fraught with danger, and leading, maybe, to serious disablement and loss of earning power. The principles of treatment are sufficiently simple once the surgical anatomy of the hand has been mastered.

Time was when it was thought sufficient to know the arrangement of the synovial bursa about the flexor tendons. A study of these governed the early treatment, the essential of which was a medial incision along the fingers, with perhaps inspired incisions in the palm of the hand here or there. The resulting prolapse of tendons, which Mr. Fifield rightly terms a calamity, and dysfunction has brought such measures into disrepute. We have learned that infective processes tend to follow certain definite paths, that they spread from one place to another in a certain ordered way, and methods have been evolved to give drainage in the best manner and to prevent extension (particularly operative extension through ignorant measures) when care might have avoided it.

It would be folly to minimize the debt that English-speaking peoples owe to KRAUSE's masterly work on this subject. The present book is, however, no slavish imitation. Mr. Fifield has evidently given a great deal of thought to his subject, and has worked on the anatomy of infection and spread in his own way. The result is a book which excels on the clinical side, and is not the offspring of an anatomical pedant. It is well and clearly written, and plainly illustrated, whilst its price is not too high. A chapter on end-results (for one can speak of end-results here with more certainty than in many disease processes) would have been interesting, for most of us have but vague ideas as to the final outcome of these cases. Speaking generally, the prognosis seems to be bad, and an interesting chapter on the effects of more rational lines of treatment remains to be written. One might also be tempted to criticize the author's advice to incise on directors passed along tendon sheaths and so forth. It is true that this simplifies the operation a little, but unless it is done very carefully and in cautious stages the director may easily pass further than is good. No doubt Mr. Fifield intended this to be understood, but since his book is primarily for the relatively inexperienced a word of warning might have been opportune.

### EMBRYOLOGY

A *Textbook of Embryology*,<sup>3</sup> by Professors JORDAN and KINDRED of the University of Virginia, affords evidence of the great interest taken in embryology and the importance attached to it by the universities of America. The book, based on the curriculum followed for the last eighteen years or so at the University of Virginia, is elegant of the thoroughness with which the subject is there studied.

*Infections of the Hand* By Lionel R. Fifield, F.R.C.S. Eng. London: H. K. Lewis and Co., Ltd. 1926. (Cr. 8vo, pp. viii + 192. 67 figures, 2 coloured plates. 5s. net.)  
*Textbook of Embryology* By Henry Ernest Jordan, A.M. Ph.D. and James Ernest Kindred, M.A. Ph.D. New York and London: D. Appleton and Co. 1926. (Roy. 8vo, pp. xii + 613. 33 plates, 473 figures. 25s. net.)

<sup>1</sup> *Comparative Physiology of the Heart*. Cambridge: Cambridge University Press, 1927.

<sup>2</sup> *Heart*. By A. J. Clark, M.C., M.D. London: Cambridge University Press. 8. 6d. net.

Naturally, being designed for the use of students, the book is somewhat stereotyped in form, and contains illustrations many of which are already familiar to us through the works of other embryologists. Perhaps the most distinctive feature of the book lies in a series of so-called exercises, actually an abridged syllabus of the curriculum followed at the University of Virginia, supplemented by upwards of thirty plates made from original drawings. Another interesting feature is the attempt to widen the horizon of the student and to foster an interest in the history of embryology by the inclusion of chapters on such subjects as teratology, eugenics, heredity, and sex determination, as well as by brief biographical references to, and portraits of, certain of the more famous of recent workers in the science.

The book while adding perhaps, little to knowledge, is an admirable compendium of the subject furnishing the student not only with all the information he requires, but also with an added stimulus to pursue independent inquiries. To anyone desiring a textbook of a size intermediate between Keibel and Mall's on the one hand, and McMurich's on the other the work under review can be safely recommended.

### MEDICAL MEN AND CRIME

DR L. A. PARRY has collected a number of trials for various crimes, mostly committed by medical men, under the title *Some Famous Medical Trials*. He begins his book with the trials of Weston and Franklin in 1615 for the murder of Sir Thomas Orelbury and ends with the prosecution of Dr Hadwen in 1924. But the cases are given in no particular order—alphabetically, chronologically, or in accordance with the nature of the charges—so that Dr Collins the abortionist rubs shoulders with Dr Watson the firebrand who was charged with treason in 1817, and the case of Dr Hunter, the quack who sued the *Pull Mall Gazette* for libel, precedes a description of the torture of John Spreull of Glasgow in 1681 for the purpose of extorting a confession of treason. Dr Parry disagrees with the view of Sherlock Holmes that when a doctor goes wrong he is the first of criminals and supports Sir James Crichton-Browne in describing such offenders as the scum of the profession. He points out that all the notorious medical poisoners such as Pritchard, Lamson, Neil Cream and Palmer made egregious blunders. The stories of the various crimes and prosecutions are presented pithily and in a very readable manner. If we have one little complaint it is that in expressing his own views on the trials of two or three hundred years ago Dr Parry does not seem to make allowance for the different standards of justice and mercy which were then held. The modern attitude towards the proceedings of the Star Chamber is of no more value historically than modern surprise at Sir Thomas Browne's views on witches.

### ISAAC NEWTON

THE memorial volume, *Isaac Newton 1642-1727*, edited for the Mathematical Association by W. J. GREENSTREET, naturally contains a great deal that only a mathematician can properly appreciate, but there are sections which appeal to the non-mathematical lay mind. Recently some notebooks have been recovered which are interesting as showing certain tendencies of Newton's mind as a boy and again in middle age and facsimiles of some pages are evidence of the minute care with which he made notes of recipes for pigments, cations, and conjuring tricks and of projects for spelling reform. As is well known Newton had an almost morbid fear of controversy or criticism and shrunk from the thought of having to defend his statement. We do not think it is known that he was myopic yet surely none but a short-sighted man could have written the minute script of his "Scheme for prosecuting counterfeiters and diminishers of the current coin."

*Some Famous Medical Trials*. By Leonard A. Parry. M.D. B.S. F.R.C.S. London J and A Churchill 1927. (Demy 8vo pp x+326 10s 6d net.)

*Isaac Newton*. Edited by W. J. Greenstreet. London G Bell and Sons Ltd 1927. (Demy 8vo pp vii+161 9 plates 16s 6d net.)

written when he was Master of the Mint. The articles on plagiarism in the seventeenth century and on Newton's metaphysics are both interesting contributions to the volume, as is also the description of his home in Lincolnshire and the King's School at Grantham which he attended with distinction. Trinity College, Cambridge and Newton are forever associated, and the notes on the condition of the college in his time will interest lovers of the University. There is a short account of the paradoxes such as Morrison better known as Zadkiel and of Charles Palmer, who published in 1793 a treatise on the sublime science of heliography, wherein he claimed to have demonstrated that the sun was a body of ice of the Hutchinsonians who denied the force of gravity of Pichard Brothers and his followers and of the flat-world cranks and many others. A full list of portraits and of portrait medals is appended. The book is well illustrated.

### KNUD FABER'S LECTURES ON MEDICINE

PROFESSOR KNUD FABER has published the four *Lectures on Internal Medicine* which he delivered a year ago in the United States of America. The first covers some of the ground of his recent Seborstein Memorial Lecture at the London Hospital on achylia, the frequency with which this absence of acid occurs, both in children and adults—clearly brought out and the view is very definitely expressed that it is dependent on gastritis which may be due to direct irritation as by alcohol, or to poison reaching the stomach by the blood stream its congenital or constitutional origin is discredited. While it is admitted that transient achylia due to nervous influence may occur, recovery from achylia is not considered to be evidence against a causal gastritis, which must be regarded as just as much a disorder as nephritis or hepatitis. In the interesting lecture discussing the intestinal origin of pernicious anaemia, the fallacy of regarding as atrophy of the intestine what are really *post-mortem* changes is demonstrated by the results of the author's observations on the microscopic appearances of contracted and dilated coils of intestine fixed in formalin directly after death. He accepts the hypothesis that achylia favours infection and intoxication with a protein and points out that a protein intoxication should be characterized by symptoms of sensitization desensitization and anaphylaxis and that the variations in the course of pernicious anaemia fulfil this anticipation. The account of benign glycosuria like the previous lectures is useful in containing references to Danish and Scandinavian work much of which may not be familiar to English readers. The concluding article "An historical sketch of medical therapy" is illustrated by portraits of Louis Magendie, Moritz Schiff and by representations of incidents connected with the copious venesections of the past.

### NOTES ON BOOKS

DESCRIPTION of different phases of the mental and physical welfare of children by various experts has been collected in a volume of the Home and School Library edited by C. W. KIDDER'S D.Sc. The health of the child as a factor in the formation of character is treated generally by Sir Bruce Porter in a thoughtful chapter while Mr Bill P. Harris contributes a most valuable account of the case of the child which ought to be read carefully by all who have concern for children. Dr G. Murray Lewis discusses the influence of light on health and the physical and mental hygiene of the pre-school child as dealt with by Dr. Eric I. R. Dr. A. G. All director of the Yale Psycho-Clinic in the U.S.A. Dr G. A. Auden considers the responsibilities of health authorities as regards children and the needs of boys and school girls as respectively examined in the hands of Dr G. E. Friend and Mr Meredith Clarendon. Training of teachers in health subjects is dealt with in a contribution by Jane Reaney D.Sc. The comprehensive character of this volume the simple and attractive style in which it

*Lectures on Internal Medicine (Delivered in the United States of America)*. By Knud Faber M.D., Professor of Internal Medicine at the University of Copenhagen. New York Paul B. Hoeber 1927. (Demy 8vo pp x+177 4s 6d net.)  
*The Mental and Physical Welfare of the Child*. Edited by C. W. Kidder M.A. D.Sc. The Home and School Library. London S. V. Partridge and Co 1927. (Pocket 8vo pp 220 6s net.)

written, and the mass of practical details will ensure its popularity among parents and teachers, for whom it has been primarily compiled

The second quarterly number of the ninth volume of the *Annals of Medical History*, edited by Dr FRANCIS R. PARKARD, opens with an account by E. B. Krumpholtz of the stigmata of St Francis of Assisi, whose portrait forms the frontispiece of the number. The "stigmata of the crucified" appeared on the hands, feet, and side of St Francis after a vision of the crucifixion two years before his death. Dr Krumpholtz, after referring to many subsequent similar cases, concludes that these stigmata are not beyond the realms of pathological possibility. A portrait of Dr Nicholas Culpeper occupies the position of honour on the cover, and this "most confident of physicians" is, together with Laennec, considered, in the light in which Kipling represented them, by Dr L. J. Birgman. Dr R. T. Williamson contributes a sketch of Peter Mere Latham, who did so much to introduce auscultation into England and put forward views on medical education deserving attention at the present day. The scientific life of William Sharpey, who first systematized physiological teaching in London, is sketched by Dr J. C. Brougher. In his scholarly and well illustrated account of Galen's studies at the Alexandrian School Dr Joseph Walsh of Philadelphia describes Galen's teachers, and says that after studying geometry, astronomy, philology, philosophy, and the logical foundations of medicine, he wrote a great treatise on inductive philosophy in fifteen books or rolls, now lost, of which he was inordinately proud. Dr Jonathan Wright contributes a long article on the Platonic Socrates and the Platonic Aristotle, which is the first instalment of an account of the evolution of the thought of Aristotle. The defence reactions—physical and spiritual, rational and distorted—adopted against the Black Death of 1348-49 are described by Dr Stephen D'Irsay, who provides a long list of references. Dr Le Roy Crummer writes on the *Anatomia Porci* of Coppi, a somewhat hazy member of the Salerno School. The last article is by Dr Frederick Eberson, on the dramatist Charles Goldoni, born at Venice in 1707, who wrote 150 comedies, some of which have a distinctly medical flavour. The energetic Editor contributes an account of Benjamin Wetherhouse—a pioneer in American medicine—and a number of discriminating book reviews.

Dr R. KING BROWN has rendered a very useful service in translating into English the second edition of Dr O. BERNHARD'S comprehensive treatise on light treatment in surgery. The book is divided into two parts, the first of which deals with light treatment generally from the historical, biological, pathological, therapeutic, and climatological standpoints. In the second part an account is given in detail of the indications for sunlight treatment in surgery, and there is a full description of heliotherapy in surgical tuberculosis. Much useful information is presented in an attractive manner, and numerous illustrations and tables are supplied. Dr Leonard Hill contributes a characteristic foreword. There are many books on the subject, but this volume can be confidently recommended, for it gives a clear account of the science and art of heliotherapy, particularly in surgery.

That Savoy is a good place for a summer holiday most English people know, and this is what a handsome volume recently received sets out to prove by means of photographs and words. It is a country of a few small towns and many villages and alpine farms. As Mont Blanc and its aiguilles are within its borders it has attractions for the climber, but it appeals also to the humbler souls content by choice or want of money to tramp over grass passes from one valley to another. The photographs, which include many of the Lake of Geneva, are well reproduced, the text is gossipy and very much a translation. It is a relief to turn from it to the preface of Mr Geoffrey Young has contributed to the English edition, in it he sympathetically discusses the philosophy of mountain rambling.

The full text of the Morris Memorial Lecture, by Professor Cannon, and hence *Characters of the Human Skin*, tetanus. The long refractory period. Race and Health, has now author remarks, is a very obvious in these columns on upon the continuous rhythmic activity the individual depends.

These are examples of but a few of the things dealt with in this small volume.

*Comparative Physiology of the Heart* By a preface by Geoffrey Cambridge. Comparative Physiology. London. Translated by Frank Price. 1927. (Demy 8vo, pp 157, 15 figures 8 6d. (62 x 92, pp 169,

## PREPARATIONS AND APPLIANCES

### Tonsillar Fossa Pressure Forceps

Mr L. Graham Brown, F.R.C.S. (London) has devised a modification of the Courtney Yorko tonsillar pressure forceps with handles curved instead of straight, and ends kidney shaped and movable to allow of more accurate adjustment to the tonsillar fossa and better compression. It can be applied to either tonsil, and can also be used in the reverse position. It has been specially designed for use in conjunction with the haemostatic tonsillar clamp, since it does not interfere, when left in position on the one tonsillar fossa, with the application of the clamp to the other tonsil and the subsequent dissection of the latter. The instrument is made by Messrs Allen and Hanburys, 48, Wigmore Street, W.

### A Pneumatic Splint Pad

A correspondent writes: In the treatment of fractures of the leg the box splint is still pretty generally and successfully used, but I have found it advantageous to use a splint pad made by the North British Rubber Company, Ltd, Edinburgh. The pad is a hollow pneumatic ring, and is used in place of the "birds' nests" of wool formerly employed. The latter, often hard and irregular, frequently cause skin irritation or ulceration, particularly behind the heel. The new splint pad is comfortable, efficient, and relieves pressure. It maintains the heel in a constant relation to the posterior wooden surface of the splint. The pad does not alter in height after the heel is laid upon it, therefore, when the fracture is satisfactorily aligned, no change in the relation of the fragments should occur during the early weeks of union. As with the "birds' nests" several pneumatic pads are required for each case of fracture treated in the box splint. The pad consists of a hollow india rubber ring, with a cold hollow 1 in by 7/8 in, the wall of which is 3/32 in thick, covered in stockinet, which prevents chafing of the skin from sweat. The inside diameter of the ring is 1 1/2 in.

## ROYAL MEDICAL BENEVOLENT FUND

At the last meeting of the Committee thirty nine cases were considered, and £624 15s voted to thirty applicants. The following is a summary of some of the cases relieved.

Daughter of M.D. who died in 1920. The applicant has been out of work for two years owing to illness. The Fund voted £60 to meet her training and other expenses to enable her to take the midwife's certificate.

Widow, aged 60, of M.R.C.S. who died in 1925. Suffers from bronchitis, asthma, heart trouble, and irreducible hernia. Her only income is from letting her furnished house from which she received £50, after paying the rates. Voted £25 in twelve monthly instalments.

Daughter, aged 65, of M.D. who died in 1878. Crippled with neuritis and dependent on her sister for attendance. This sister has had to be removed to a mental home, and the applicant is now entirely dependent on paid attendant. Her only income is £74 from investments augmented by friends' help. Voted £5 and £25 in twelve monthly instalments.

Widow, aged 41, of L.R.C.P. who died in 1926. She was left with two children aged 7 1/2 and 6 1/2, and asked help for the children while young. Voted £20 in four quarterly instalments.

L.R.C.P. and S.E.d. 1891, aged 72. Nearly blind through diabetes is dependent on the charity of his landlady. His wife, upon whom he was entirely dependent, died last year. The Officers' Association gave help and the Fund voted £8 and £40 in twelve monthly instalments.

M.R.C.S. who died in 1921, leaving three sons aged 11, 9 and 6. One is at Epsom and the other two at an orphanage. These children are dependent on relatives, and help is asked to meet holiday expenses. Voted £15.

Daughter, aged 25, of M.R.C.S., who was trained as a teacher and has had a post for two years at an elementary school. To enable her to get a post in a secondary school she asks for help towards a year's training in needlework, which will cost £125. It was decided, after careful consideration, to vote £40 towards the fees and maintenance.

Subscriptions may be sent to the Honorary Treasurer, Sir Charles Symonds, at 11, Chandos Street, Cavendish Square, London, W.1.

The Royal Medical Benevolent Fund Guild still receives many applications for clothing, especially for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second hand clothes and household articles. The gifts should be sent to the Secretary of the Guild, 58, Great Marlborough Street, W.1.

# British Medical Journal.

SATURDAY, AUGUST 6TH, 1927

## LUNACY LAW AND LAWYERS

No one can justly assert that the greatest glutton for facts and opinions about lunacy administration has not had spread before him an ample feast in this issue of the JOURNAL and in the SUPPLEMENT for last week. Some readers may perhaps be inclined to think that there has been too much of one subject, but it seemed expedient to present the Memorandum of the British Medical Association on the Report of the Royal Commission on Lunacy, the debate in the Annual Representative Meeting at Edinburgh, and the discussion in the Section of Mental Diseases as nearly simultaneously as possible.

Broadly regarded, very considerable resemblance will be found between the criticisms and recommendations of the Memorandum and those of Professor Robertson in opening the discussion in the Section. He is bred to the administration of the law as it is in Scotland but he has made himself well acquainted with the law in England, which he thinks very inferior. The difference is in a matter of principle. Under the Scottish law the position of the medical profession in the management and treatment of persons of unsound mind, or alleged to be so, is paramount, in England and Wales it is subordinated to an erroneous legal conception that has helped to mislead public opinion, which has never outgrown mediaeval ideas about mental disorders.

The English lawyers of 1890 acted *a priori* did not study the facts of life, and allowed themselves to be so obsessed by the problem of the liberty of the subject and the fear of improper detention that for one thing, they closed their minds to the really fundamental difference between remedy and custody. Judging by some of the remarks dropped during the hearing of *Harnett v Fisher*, the attitude of many lawyers is much the same now. Professor Robertson did not mince his words. The English Act of 1890, he said, though designed for the welfare of the insane person, has turned out to be to his detriment, and thus affords one more example of how laws enacted with the object of reducing the sum of human misery have, in fact, increased it.

Professor Robertson's remedy for the present discontent is to assimilate the English law to the Scottish, and he claims that the recommendations of the Royal Commission would go some way towards this. So does the Memorandum in effect. But it does more than discuss the reforms necessary; they will require legislation, which in spite of Sir Frederick Wilks's hopes may not soon be introduced there must therefore, be some delay, and, moreover, any legislation proposed will almost certainly encounter much opposition, parliamentary, legal, and even public opinion being what it is. The Memorandum also gives sound advice (para 60) to practitioners on the precautions they ought to take to make sure that they shall be able to recall, perhaps years after the event, the reasons why they acted as they did. It refers also in the following paragraphs (61 and 62) to some things done by experts, in support of allegations of negligence, which had better not have been done.

The opposition in the Representative Meeting to the

acceptance of the Memorandum as an equivalent to a report from the committee would seem to have been due in the main to a feeling that members had not had sufficient time for consideration of a document containing arguments and recommendations of great importance to the public, and to the profession in its everyday life—a document, moreover on which the Association would be almost pledged to seek legislation. There are passages in the Memorandum which render it plain that the committee itself did not consider that it had finished its work, it makes specific reference to the resolution of the Representative Meeting last year (about Harnett v Fisher) instructing the Council to take steps to protect the interests of the medical profession, and mentions the *Hume Spry* case and that of *de Freville v Dill*. The Chairman of the committee, in fact, asked that the Memorandum should be approved and referred to the Council so that no harm seems to have been done by the decision of the Representative Meeting which referred the Memorandum to the Council with the request that it should appoint a committee for further consideration of the Royal Commission's report.

Meanwhile, it can be said without hesitation that the profession is deeply indebted to the committee for preparing a very valuable Memorandum which must have cost its members, and particularly its chairman, Dr Langdon-Down, much time and labour. The Association is fortunate in having members ready to give their services so freely and competent to handle a subject of great difficulty and complexity with so much ability and in language so clear and temperate.

## THE METABOLISM OF TUMOURS

THOUGH reiteration may often become a weariness to the flesh it is sometimes salutary to the spirit. Repetition may not be the highest service of faith, but it has been found effective in keeping the inconstant mind of man from turning after false gods. This has been the experience of all the prophets. So since science also is grounded in faith, we need make no apology for the repetition of a trite observation.

The problem of cancer is bound up in the wider problem of the nature of growth. To the lay mind at all events, there is no question but that the most disconcerting characteristic of a tumour is that it grows. The immediate practical problem of the pathologist is, doubtless, the discovery of the agent responsible for imparting to normal cells their tendency towards disordered growth but he will agree that the fullness of the problem will scarcely be apprehended until we are in a position to describe the processes of normal and malignant growth in precise physical definitions. In particular, it is an urgent question whether the growth of a neoplasm represents an intrinsic departure from the physiological routine of living cells, or whether it is but an undisciplined exhibition of normal metabolic processes. Every serious inquiry therefore, into the intimate nature of growth processes in normal and malignant tissue is or the deepest concern to medicine. Some time ago we published a review of the volume on the metabolism of tumours by the brilliant German biochemist Otto Warburg, being the collected papers of original work prosecuted over a period of some years.<sup>1</sup> The great significance of the work, the appearance of further important extensions to the story and the first signs of an awakening

<sup>1</sup> *Über den Stoffwechsel der Tumoren*. Von Otto Warburg. Berlin J. Springer 1926. (Roy. 8vo pp. 253, 22 figures, B. 1. 6. 0 to 1 s. 6d.) A review appeared in this JOURNAL on Dec. 10, 1926. An extensive critical review by Mr. R. K. Cannon was published in the *Cancer Review* July 1927.

interest in this country, justify our returning to the subject in some greater detail.

Growth in physical terms means work. It means the storage of a definite amount of chemical energy in the material and structure of the cell. Growth, therefore, is conditioned by the nature and extent of the metabolic activity of the growing cells, and a comparison of the sources of energy of normal and malignant cells is a logical and urgent subject for inquiry. Such are the premisses from which Warburg has projected his investigations and his argument. One further principle is fundamental to the latter. We are accustomed to regard the ability to live and grow in the absence of oxygen as the peculiar prerogative of a limited number of the simple unicellular organisms. Recent progress in physiology has demonstrated how unjust is this reflection on the versatility of the cells of the higher animals. Whilst it is true that the higher animals depend constantly on an adequate supply of oxygen for their continued existence, it is also true that a pronounced anaerobic habit persists in many of the activities of individual tissues. They exhibit that form of fermentative activity which has been called glycolysis—the anaerobic decomposition of carbohydrate into lactic acid. This reaction liberates energy. We have, therefore, to distinguish two potential sources of energy for the cells of the higher animals. One is the combustion of carbohydrate by respiration, and the other the fermentation (“glycolysis”) of carbohydrate. The investigations of Warburg were directed essentially to the determination of the relative contributions of these two processes to the energy metabolism of various normal and malignant tissues. The argument, it will be seen, is by no means abstruse, but the technique employed is difficult and involved, and thus, together with the fact that the studies were made on tissues *in vitro*, has prejudiced that attention, repetition, and extension which the results undoubtedly merit.

Notable differences have been laid bare in this *in vitro* metabolism of various types of cells. Normal resting tissues show a high respiratory and a low glycolytic rate, embryonic tissues exhibit high respiration and high anaerobic glycolysis, and neoplastic growths have a lower respiration and a higher anaerobic fermentation. In the presence of oxygen the glycolytic rate is in all cases depressed below that evidenced under anaerobic conditions. In a recent paper Warburg<sup>2</sup> makes a very plausible argument for the conclusion that the degree to which glycolysis is depressed bears an exact quantitative relation to the amount of oxygen consumed in respiration. In normal and embryonic tissues the latter is sufficiently great, and the anaerobic glycolysis sufficiently low, to result in the almost complete suppression of fermentation in the presence of oxygen. Not so is it with malignant cells. There remains, in their case, a considerable glycolytic activity under aerobic conditions. Warburg, who describes this as the ‘excess fermentation,’ shows that it is, in the case of tumours, sufficiently great to make an important contribution to the total energy metabolism of the tumour under aerobic conditions, and that it is a value upon which may be based a useful classification of tissues which follows closely their growth rate and malignancy. A number of interesting exceptions to this classification have been disclosed, and these and some technical difficulties make the method of doubtful diagnostic value, although it remains of supreme physiological importance.

To what practical conclusion are we led? It would

be tempting to surmise that the malignant cell is peculiar in its ability to derive energy for survival and growth by a fermentation process, even in the presence of oxygen. To relate such studies as these to the growth of a tissue is, however, very difficult, and at present little more has been achieved experimentally than to show that the survival of a tumour within the host does seem to be conditioned by the peculiarities of metabolism which have been defined by the studies *in vitro*. This is no mean achievement.

If these conclusions are true they would seem to offer little hope for the experimental control of malignant growth. It would be expected that cells which have a dual metabolic habit would be more difficult to restrain than normal cells with a purely respiratory metabolism. Some preliminary experiments on the intact animal, however, suggest that the situation is more promising than could be inferred. Reduction of the oxygen tension to which tumour-bearing animals were submitted resulted in a few hours in the death of the great majority of the neoplastic cells without injury to the normal tissues. Warburg finds an explanation for this anomalous result in the conclusion that the blood supply—that is, the supply of oxygen and carbohydrate—to the tumour is little more than adequate to its needs under ordinary conditions. Normal cells are more liberally treated. When oxygen or carbohydrate is experimentally restricted the tumour will be starved while yet the normal tissues are above the poverty line.

These observations are but a beginning, but they open wide the field for experimentation on the whole animal. They command attention to the whole subject of Warburg's thesis.

In conclusion, what shall we say of the origin of cancer? Warburg suggests an intriguing hypothesis. A tissue is a community of cells which exhibit wide individual differences in their respiratory and fermentative capabilities. Some few of the cells may be regarded as having the metabolic characteristics of neoplastic cells. These, being limited in number, will make no significant contribution to the aggregate metabolism of the whole tissue. Let, however, a local condition of anoxæmia supervene, and there will result the extinction of all the cells except those few that are able to derive the energy for survival and growth from fermentative activity—the potential cancer cells. These will survive, proliferate, and from them will derive a malignant growth. “Limitation” becomes “anoxæmia.”

Warburg challenges both physiologist, pathologist, and clinician. The repetition and extension of his work in this country should not be longer delayed.

#### THE BRITISH ASSOCIATION

The British Association for the Advancement of Science will meet in Leeds this year. The inaugural general meeting will be held on the evening of Wednesday, August 31st, when the President, Sir Arthur Keith, M.D., F.R.S., conservator of the museum of the Royal College of Surgeons of England, will give his presidential address on Darwin's theory of man's descent as it stands to-day. The meetings of the Sections will begin on the following day, September 1st, and will continue until Tuesday, September 6th. The concluding general meeting will be held on September 7th. There will be twelve Sections. The president of the Section of Physiology is Dr C. G. Douglas, F.R.S., of Oxford, well known for his researches on respiration and kindred physiological subjects. He will give his presidential address on September 2nd, and has chosen for

his subject the development of human physiology. The president of the Section of Psychology is Dr. William Brown, Wilde reader in mental philosophy in the University of Oxford, and consulting psychologist to the Bethlem Royal Hospital, his presidential address on mental unity and mental dissociation will be given on Monday, September 5th. The president of the Section of Anthropology is Professor F. G. Parsons, lecturer on anatomy at St. Thomas's Hospital, who in his address will discuss the Englishman of the future. The University of Leeds at a special degree ceremony on December 6th will confer the honorary degree of LL.D. on Sir Arthur Keith, and that of D.Sc. on Dr. J. S. Haldane, F.R.S. of Oxford. Two evening discourses to members will be given in the Albert Hall: the first on the evening of Friday, September 2nd, by Professor R. A. Millikan, of the California Institute of Technology, on cosmic rays, and the second on Monday, September 5th, by Dr. F. A. E. Crew, director of the Animal Breeding Research Department and lecturer in genetics in the University of Edinburgh, on the germ plasm and its architecture. Public lectures will be arranged in Leeds and neighbouring towns. A civic reception will be held in the Art Gallery on the evening of September 1st, and a reception will be given by the University of Leeds on the evening of September 6th. A large number of excursions have been arranged for Friday, September 2nd, for Saturday, September 3rd, and Sunday, September 4th, and on Monday, September 5th, a party will go by way of Harrogate to Plumpton Rocks. Leeds is a city of many industries and visits to works and factories in and near the city have been planned.

#### THE VOLUNTARY HOSPITALS COMMISSION

At the thirty-sixth meeting of the Voluntary Hospitals Commission on July 6th, Lord Onslow, Lord Clivedon, Sir Robert Bolam, Dr. Brist, Mr. Wade Deacon, and Dr. Menzies were present. Memorandums summarizing the position regard extensions of accommodation in voluntary hospitals were considered. Dr. Menzies inquired how much of the additional accommodation indicated in the tabular statements could be regarded as strictly new accommodation and not merely beds released for their original use after having been diverted to special purposes—for example in connexion with war services. The chairman said that an attempt should be made to verify the information which had been collected by the Commission's staff, and he suggested that a draft report might be prepared and the appropriate portions circulated to the local committees for their observations. The draft would then be revised in the light of the information obtained from the local committees and circulated to the Commission for their observations. The Commission approved this course and the chairman suggested that a map should be prepared to show particularly the areas in which little additional accommodation had been provided. Sir Robert Bolam raised the question of the continuance of the Commission and asked that an opportunity should be afforded for discussing its future. The chairman said that the Minister desired the Commission to continue in existence particularly as a link between the Government and the local committees. It was thought that the Commission might give the Government valuable help in connexion with the redistribution of hospital accommodation if a measure of Poor Law reform were passed. Sir Robert Bolam asked that the consideration of the continuance of the Commission might be put on the agenda for the next meeting.

#### MUSIC AND MILK

Among dairy folk there is a belief that a cow will yield more milk to a singing milker than to one who omits such "soothing stimulation"; indeed, the matter seems to go further, for some cows are said to discriminate, only

giving full measure of it may be any milk at all in response to a particular melody. A practical trial of the effects of music was made in Germany in 1924 concerns being provided in the stalls at milking time on certain days. Secretion of milk takes place in two phases—slowly between milkings and rapidly (two-thirds of the total) during these operations. It was found that on concert days this latter secretion was increased by 6 per cent compared with tuneless days, when the instrument employed was the gramophone or violin. It is hardly surprising that so pacific a function as milk giving was not favourably influenced by the martial strains of the trumpet. On the concert days the total solids and fat of the milk were increased in amount but lessened in percentage. Nebert and Koch<sup>1</sup> of Halle have tried to apply these observations to wet nurses, who were taken from their homes and placed in quiet comfortable surroundings; they gratefully responded to this treatment by an increased yield of milk, but they seem to have been less musical than the cows for no further increase is noted on days when a gramophone played Handel's Largo and the Tales of Hoffman during resting periods, and brisk marches during actual nursing, perhaps instrument company, and type of music were not happily chosen. The women tested all had a good natural flow of milk. Nebert and Koch mean to make further tests with women whose milk is failing or scanty. Now that broadcasting has made music available throughout town and country, perhaps large scale experiments may be made in dairy farms and infant clinics, but it will be harder than ever for the B.C. to frame generally acceptable programmes if the requirements of the milk trade and of nursing mothers have to be considered. So much for the favourable influence of music. Is there risk of harmful effect? Little positive evidence is available but the German trials with the trumpet suggest caution, and even before the days of saxophone and jazz band we had heard of the tune that the old cow died of, and a well known Scottish divine need to tell how in boyhood his cornet playing was first banned from the manse because it spoilt his father's sermons, and later from the lay loft because the cows, in the byre below gave sour milk. Recent Chinese law has specifically forbidden the sale of milk having blue, purple, and other colours. Can it be that such startling dairy phenomena have resulted from the effects of Chinese music upon imported milk cows?

#### THE FAT SOLUBLE VITAMINS IN MILK

DURING the past decade evidence has accumulated steadily to show the importance to the health of infant of an adequate supply of fat soluble vitamin. This fact has naturally prompted many investigations into the factors influencing the fat-soluble vitamin content of cow's milk. The earlier experiments were somewhat inconclusive because they did not distinguish clearly between vitamin A, the growth-promoting factor and vitamin D, the anti-rachitic factor. It is now known that green vegetables contain a rich supply of vitamin A but relatively little vitamin D. Feeding experiments on cows (see 1924-Chick and Peto 1926) showed that a ration rich in green fodder increased the vitamin A content of milk but had only a slight effect on the anti-rachitic factor. The problem of practical importance is to find a diet which will ensure that the cow's milk contains an adequate supply of both vitamins. The milk of pastured cows contains both vitamins but the difficulty is to produce an adequate content of vitamin D in winter milk. Goldenroes, and Zila have found that, whereas green fodder in the winter ration of the cow raises the vitamin A content

<sup>1</sup> Nebert and Koch, *Leit. f. f. Antirachit. v. d. 1925* 33 p. 62.

<sup>2</sup> Goldenroes and Zila, *Die Milch* 1926 p. 106.

but not the vitamin D content, yet addition of cod-liver oil to the cow's ration raises both the vitamin A and the vitamin D content of the milk, but unfortunately large doses of cod-liver oil decrease the fat content of the milk. These results are, however, of practical importance, since they indicate a method by which cow's milk of fairly high antirachitic potency can be obtained in winter. Moreover, they provide experimental support for the administration of cod-liver oil to nursing mothers to produce an antirachitic action in breast-fed infants.

#### ETHNOLOGY AND DISEASE

In a paper written shortly before his untimely death, Dr S. T. Dalling showed how the study of the geographical distribution of human parasites might throw light on the place of origin and migrations of races of mankind. Conversely, Ramsay<sup>1</sup> has invoked the aid of ethnology in support of his view of the origin of yaws among the tea-garden coolies of Assam. Powell believed that yaws in Assam could be traced to the arrival from Ceylon in 1877 of an infected coolie girl. There seems little doubt that this girl and her sisters, whom she infected, were the cause of a considerable local spread, but Powell would trace the spread throughout and even beyond Assam to the same source. Ramsay admits that such importations occur, but he noticed that those tea-gardens where yaws occurred were generally near the villages of hill tribes—Nagas, Kukis, Lushais, and Manipuris—or there was evidence of contact with these tribes in bazaars. There was, in fact, a Manipuri village in the middle of Powell's tea-gardens. When these tribes were investigated, yaws was found to be rampant among the first three and common in the fourth. In some Kuki villages practically every person was suffering or had suffered from yaws, though the disease was thought by a local missionary to be syphilis. This prevalence was very striking as compared with the comparative scarcity of *framboesia* among tea-garden coolies. The history of these tribes has been studied with the aid of several ethnological authorities. Immigration to the Assam hills has been from south to north. The Nagas appear to have arrived first of the present tribes, they show definite affinities with the natives of the Pacific Islands, and still have a suggestive fondness for marine shells, they are of Caspian stock mixed with Negrito. The Kukis, of Alpine (or Palaeo-Alpine) and Mongolian stock, came later from China or Tibet, and they too have absorbed much Negrito blood, as can plainly be seen in their women. The Lushais are believed to have come from the Chin Hills of Burma in the eighteenth century, and they and the Kukis are certainly of the same race as the Burmese Chins. The ethnological facts seem to connect the yaws of Assam with that disease in Burma, Malaya, and the Pacific Islands, and Hutton, who is quoted by Ramsay, suggests that the link is the negroid blood with which yaws is associated over most of the world, though if that blood has acted as the distributing agent the disease must have been present in Assam before the arrival of the invading tribes, for the aboriginals of the Assam hills were Negritos of Andamanese type. Ramsay propounds the possibility of a common origin of yaws for all the Far East, or perhaps for the Old World. It seems not impossible that links with the New World might be found.

#### SWINE ERYSIPELAS IN MAN

Swine erysipelas is a disease of pigs by no means uncommon in this country, and the cause of a considerable loss to farmers. It is characterized by the appearance of red, diamond-shaped blotches on the skin, and by the development of vegetations on the valves of the heart. The latter lesion has in recent years attracted the attention of com-

parative pathologists, mainly because of its resemblance to somewhat similar lesions associated with cardiac rheumatism. Its resemblance to that condition has proved to be more apparent than real, but it has been found to be very similar to the ulcerative endocarditis of human beings caused by streptococci, gonococci, and pneumococci. In this, as in swine erysipelas, the inflammation of the valve proceeds from the surface inwards, whereas in rheumatic carditis the inflammation commences in the depth of the valve and spreads towards the surface. The disease in pigs is caused by a specific bacillus, and numerous instances have been recorded in which human beings were infected with it, and developed an erysipeloid condition of the skin. The infection in man generally occurs through inoculation, and there is a tendency to regard the erysipelas of Rosenbach as identical with it. Klauder, Richter, and Harkins<sup>2</sup> have recently made a detailed study of a very similar condition occurring in fish handlers. Rosenbach's erysipeloid is seen most often in persons who handle game and fish, and is as a rule confined to the hands near the point of inoculation. The lesion consists of a sharply defined, slightly raised, reddened area, with few if any general symptoms, it has an incubation period of one to six days. Swine erysipelas in man is rather more severe in its symptoms, and lymphangitis may be present. The existence of a heart lesion has not yet been demonstrated. The series of outbreaks recorded in this paper occurred in fishermen on the sea coast of New Jersey. The lesions commenced within twenty-four hours after a bite from a fish or a prick from the spine or scale, and the disease lasts from four to six weeks. The sore is conspicuous and painful, the lymph glands are affected, and headache and fever are common in the early stages. Similar but milder symptoms are seen in those who handle the fish later. This erysipeloid condition is quite different from the other skin diseases of fishermen such as dermatitis from nets, etc., and urticarial eruptions associated with new hemp nets or from contact with fish such as the Portuguese man-of-war, and "stings" of various fish such as electric eels and catfish. Three strains of this bacillus are generally recognized—human, porcine, and murine, the authors believe that it may be necessary to add a fourth—a piscine—which is pathogenic to white mice and pigeons, but not to field mice, apparently it has a high virulence to man. The bacillus of swine erysipelas (*B. rhusiopathiae* or *B. marsepticus*) is apparently pathogenic to all groups of vertebrates, but its virulence varies with the different animals, and may be altered by passage. Man is relatively resistant to ingestion, but may be infected through the skin. It would seem that we may recognize at least three human conditions due to this organism: the erysipeloid of Rosenbach, "fish poisoning," as this condition is called locally, and finally human swine erysipelas. These conditions differ only in severity, the last being the most acute.

#### THE PERIODS OF EUROPEAN MEDICINE

In a paper read before a meeting of the Devon and Exeter Medico-Chirurgical Society on February 17th, 1927, and reported in our columns on March 5th (p. 429), Dr W. Gordon of Exeter reviewed in the brief space of an hour the medical history of twenty-five centuries. The text of this scholarly sketch, "The periods of European medicine," has now been privately printed, and bears eloquent evidence of the author's literary grasp and reading. But particular attention may now be directed to his method of treating the subject—namely, by making natural divisions of the centuries into periods, and by showing the reactions of medicine to changes in the environmental conditions. Three great natural periods are distinguished—the rise, mainly Asiatic-Greek, from 600 B.C. to 200 A.D.;

<sup>1</sup> Ramsay, E. C., *Trans. Roy. Soc. Trop. Med.*, April, 1927, p. 506.

<sup>2</sup> *Arch. Dermat. and Syph.*, xiv, 662-678.

the present, from the death of Galen to about 1500 A.D., when the Italian renaissance reached and revived medicine, and the reascend, from that time to this. Each of these three main periods has three subdivisions, thus the rise starts with the pre-Hellenic phase, lasting three centuries, is followed by the Alexandrian epoch of two centuries, and then by three centuries of Roman activity. The pause, commencing with a gap of 150 years of chaos, included the Byzantine portion (324-700 A.D.), beginning with the writings of Oribasius, the Arabian (700-1300 A.D.), and a third subperiod which Dr Gordon associates with magnificent architecture, carving, and glass. The reascend begins with a North Italian subperiod of a century's duration, and then passes into the trans-European phase down to 1840, when what is called the pre-Cosmic subperiod is reached. These divisions and subdivisions are made clear to the eye by a diagram in the reprint. Stress is laid on the greater sensitiveness exhibited by medicine to liberty of thought, and on the later maturity of medicine as compared with art or letters. In addition to this general consideration of the evolution of medicine, Dr Gordon gives much detailed information about the men who have played prominent parts in the history of our art and science.

#### A NEW DIPLOMA IN ANTE NATAL CARE, MIDWIFERY, AND INFANT WELFARE.

THE Examinations Committee of the Society of Apothecaries of London as recorded in our issue of July 30th (p. 193), has decided to recommend the governing body to institute at an early date a special diploma in ante-natal care, midwifery, and infant welfare. It would be granted to registered medical practitioners who had been engaged in post-graduate study of the subjects, both in practice and theory, a high standard of professional knowledge would be ensured by a stringent examination. The diploma is intended to meet the needs of the general practitioner who wishes to show that he possesses knowledge and experience in these subjects of a higher grade than that required or legal qualification. It is not proposed to limit the diploma to licentiates of the Society of Apothecaries, but to throw it open to all registered medical practitioners.

#### MR F G HALLETT

MR F G HALLETT has notified his intention to retire in December next from the office of secretary of the Conjoint Examining Board in England. When this resignation takes effect it will bring to an end an active career of fifty years passed in the service of the medical profession. Mr Hallett joined the office staff of the Royal College of Surgeons in December, 1877, became a assistant secretary to the College in 1882, and was appointed secretary of the Conjoint Examining Board in England when that body was instituted in January, 1885. The Committee of Management of the Examining Board, with regret, recommended the Colleges to accept Mr Hallett's resignation and the Royal College of Physicians at its meeting last week passed unanimously and cordially a resolution of thanks to Mr Hallett. Mr Hallett has won the esteem and friendship of succeeding members of the Committee of Management and of the Board of Examiners. He has always been remarkable for his courtesy and readiness to help and in the course of his long service has become a mine of information with regard to the conduct of examinations—in fact, his reputation is world wide, he visited the United States some years ago to give advice on the subject and has also given his help with regard to the adjustment of such matters in Egypt. In consenting to illuminate the Roll of Honour of the British Medical Association Mr Hallett disclosed one of his hobbies. This Roll, which is now preserved in the Library in the Association's House contains

the names of the members who gave their lives for King and country in the great war, and when the King and Queen in 1925 came to open the House they visited the Library and inspected the Roll. They congratulated Mr Hallett on its completion, and asked him how many hours he had spent on the task. The reply was 430. On this occasion the King accepted from Dr J A Macdonald (Chairman of the Journal Committee) a copy of the Roll, bound in morocco, each page being reproduced by photo-mechanical means. All who have worked with Mr Hallett, or have known him in other capacities, will wish him many years of life in his country home.

#### A FRENCH VIEW OF EARLY MEDICAL EDUCATION

WITH the ever-increasing amount of knowledge the problems of medical education and especially of the standard to be required before entry to the profession, and the organization of the preliminary teaching of the basic sciences—chemistry, physics, and biology—are rightly receiving anxious attention. The inevitable tendency now is to throw back on to the last year or more of school life the teaching of these subjects, and thus to obtain more time in the overlaid curriculum for clinical teaching. This course, however, entails some degree of early specialization, and so may encroach on the acquisition of a general education in letters. The amount of physical and chemical knowledge required for medical education has, of course, greatly increased, and with the object of finding a means whereby this end could be attained without, if possible, encroaching unduly on the opportunities for general culture, a committee of the Académie de Médecine de Paris was appointed in December, 1926. The committee in its report has recommended that, on the one hand, students intending to take up medicine should be obliged to present two baccalaureat diplomas—one for compulsory Latin and optional Greek, the other for mathematics, and, on the other hand, that the scientific instruction given in the preparatory year of medical studies should be provided in the Faculty of Medicine and the medical schools, instead of, as at present, in the Faculty of Science.

#### THE HUGHLINGS JACKSON LECTURE.

ONE of the events of the conference in London between the Section of Neurology of the Royal Society of Medicine and the American Neurological Association in London—of the opening of which we gave some account last week—was the delivery by Dr Charles L Dana of the Hughlings Jackson Lecture. Dr Dana said American neurologists came first under the influence of Charcot, then were attracted by Erb, Krausmaul and the Germans and a little later perhaps felt the inspiration of Jackson's work. His own earliest recollection of American neurology was as an intern, after that he received an appointment to a neurological clinic. Of the four men in New York in those days who were most active in psycho-neurological matters and gave a certain forceful touch to the subject one was Dr Edward C Spitzka, finely trained in anatomy under Meynert of Vienna who was very scornful of American work, and violently antagonistic to the United States methods of caring for the insane at that time. Another, Dr W A Hammond, was the dominant personality of the day, but a man of much more original and brilliant type was Dr George M Beard who first proclaimed and consistently taught the importance of noting and evaluating subjective symptoms, no equivalent decreased the serious characteristics of American life and of the American people, and was the first to indicate the importance to the State and the community of preventive methods along this line. Dr Dana believed that this was the most important angle

problem in neurology and sanitation to-day. At the time of his early acquaintance with Beard, Griffield, the President of the United States, was assassinated by Guteru Di Duna, in conjunction with Di Berid, examined Guteru, assisted at his necropsy, received part of the brain, and made a formal report. These were the days when Lombroso flourished in Italy, and when Moritz Benedict, in Vienna, had just written upon the cerebral fissures. The fourth man in the New York group was Di Edward C Segun, by far the best trained of the American neurologists of that day. His influence in developing precise methods of examination, his interest and skill in therapeutics, and his devotion to his patients, made a great impression and greatly helped to improve neurology. He was a believer in drugs, as were Beard and Hammond, and was inclined to give large doses. It was the period when potassium iodide was given to the extent of 300 or 400 grains daily. Tincture of iron women was used by Segun in doses of half a drachm or more, and hyoscine up to one-sixth of a grain. Bromides were also given massively, and periodic bromidization was employed in epilepsy. Di Duna thought the practice admirable in trained hands. The American Neurological Association was organized, and a *Journal of Nervous and Mental Disease* was founded at the end of the nineteenth century, the prime mover being Di Jewell of Chicago. Thirty years ago in New York there were only three nerve clinics and no special hospital. Now there were many well attended clinics, a neurological hospital, and several important neurological departments in the general hospitals. Preventive neurology was a phrase of work that was of high importance, though it had been greatly neglected. There were many chronic nervous diseases, such as paralysis agitans and disseminated sclerosis, with an enormous literature which ignored the question of prevention. Americans were a nervous race, using the term in the sense that nervousness meant an exaggeration of physical and mental activity. Nevertheless, the nervous disposition was the highest form of constitutional make-up, on the whole, it was well to have some degree of nervousness as an impelling force in a nation and community. He was opposed to the prevention of nervousness by the development of lymphatic and melancholic temperaments.

#### THE COMPILATION OF VITAL STATISTICS IN PORTUGAL

The first census of Portugal on a modern plan, comprising locality, age, sex, civil condition, occupation, and other points, was carried out in 1864, and the second in 1878. In 1887 it was affirmed by law that there should be a decennial census, the years selected being those whose terminal digit was a zero. This enactment has been three in operation—in 1900, 1911 (replacing 1910, which witnessed the revolution), and 1920. At the census of 1920, for which December 1st was the appointed day, the household schedules, as narrated in a recent account by the League of Nations of the official procedure, were distributed and recovered by census agents, who passed them on, after scrutiny, to the local census committees, and the local committees in turn transmitted them, after inspection, to the Director-General of Statistics in Lisbon. The data so gathered formed the raw material for the report of the census for 1920 which has been published in four volumes. The Director-General, in his preface to the report, states that locally appointed agents stuck for higher remuneration on the eve of the appointed day, that in some cases they did not take the census on the date fixed, and that they omitted to recover a proportion of the schedules they had distributed. He indicates that the organization by the local census committees was inefficient, and may be presumed to have viewed the figures supplied to him with some tincture of misgiving. He reports that the population of
